3.6 Abstract Machines

3.6.1 The Chemical Abstract Machine

The chemical abstract machine, or the CHAM, is both a model of concurrency and a specific operational semantics style. The states of a CHAM are metaphorically regarded as chemical solutions formed with floating molecules. Molecules can interact with each other by means of reactions. A reaction can involve several molecules and can change them, delete them, and/or create new molecules. One of the most appealing aspects of the chemical abstract machine is that its reactions can take place concurrently, unrestricted by context. To facilitate local computation and to represent complex data-structures, molecules can be nested by encapsulating groups of molecules as sub-solutions. The chemical abstract machine was proposed as an alternative to SOS and its variants, including reduction semantics with evaluation contexts, in an attempt to circumvent their limitations, particularly their lack of support for true concurrency.

CHAM Syntax

The basic molecules of a CHAM are ordinary algebraic terms over a user-defined syntax. Several molecules wrapped within a membrane form a solution, which is also a molecule. The CHAM uses the symbols \( \{ \) and \( \} \) to denote membranes. For example, \( \{ m_1 \ m_2 \ldots \ m_k \} \) is a solution formed with the molecules \( m_1, m_2, \ldots, m_k \). The order of molecules in a solution is irrelevant, so a solution can be regarded as a multi-set, or a bag of molecules wrapped within a membrane. Since solutions are themselves molecules, we can have arbitrarily nested molecules. This nesting mechanism is generic for all CHAMs and is given by the following algebraic CFG:

\[
\begin{align*}
\text{Molecule} & ::= \text{Solution} | \text{Molecule} \bowtie \text{Solution} \\
\text{Solution} & ::= \bag{\text{Molecule}}
\end{align*}
\]

The operator \( \bowtie \) is called the airlock operator and will be discussed shortly (under general CHAM laws), after we discuss the CHAM rules. When defining a CHAM, one is only allowed to extend the syntax of molecules, which implicitly also extends the syntax that the solution terms can use. However, one is not allowed to explicitly extend the syntax of solutions. In other words, solutions can only be built using the generic syntax above, on top of user-defined syntactic extensions of molecules. Even though we do not formalize it here (and we are not aware of other formulations elsewhere either), it is understood that one can have multiple types of molecules in a CHAM.

Specific CHAM Rules

In addition to extending the syntax of molecules, a CHAM typically also defines a set of rules, each rule being a rule schemata but called a rule for simplicity. A CHAM rule has the form

\[ m_1 \ m_2 \ldots \ m_k \rightarrow m'_1 \ m'_2 \ldots m'_l \]

where \( m_1, m_2, \ldots, m_k \) and \( m'_1, m'_2, \ldots, m'_l \) are not necessarily distinct molecules (since CHAM rules are schemata, these molecule terms may contain meta-variables). Molecules appearing in a rule are restricted to contain only subsolution terms which are either solution meta-variables or otherwise have the form \( \{ m \} \), where \( m \) is some molecule term. For example, a CHAM rule cannot contain subsolution terms of the form \( \{ m \ s \} \), \( \{ m_1 \ m_2 \} \), or \( \{ m_1 \ m_2 \ s \} \), with \( m, m_1, m_2 \) molecule terms.
and $s$ solution term, but it can contain ones of the form $\{m\}$, $\{m_1 \triangleleft \{m_2\}\}$, $\{m \triangleleft s\}$, etc. This restriction is justified by chemical intuitions, namely that “matching” inside a solution is a rather complex operation which needs special handling (the airlock operator $\triangleleft \triangleleft$ is used for this purpose). Note that CHAM rules are unconditional, that is, they have no premises.

**General CHAM Laws**

Any chemical abstract machine obeys the four laws below. Let CHAM be a chemical abstract machine. Below we assume that $mol$, $mol'$, $mol_1$, etc., are arbitrary concrete molecules of CHAM (i.e., no meta-variables) and that $sol$, $sol'$, etc., are concrete solutions of it. If $sol$ is the solution $\{mol_1, mol_2, \ldots, mol_k\}$ and $sol'$ is the solution $\{mol'_1, mol'_2, \ldots, mol'_l\}$, then $sol \uplus sol'$ is the solution $\{mol_1, mol_2, \ldots, mol_k, mol'_1, mol'_2, \ldots, mol'_l\}$.

1. **The Reaction Law.** Given a CHAM rule

   $m_1 m_2 \ldots m_k \rightarrow m'_1 m'_2 \ldots m'_l \in \text{CHAM}$

   if $mol_1, mol_2, \ldots, mol_k$ and $mol'_1, mol'_2, \ldots, mol'_l$ are (concrete) instances of $m_1 m_2 \ldots m_k$ and of $m'_1 m'_2 \ldots m'_l$ by a common substitution, respectively, then

   \[ \text{CHAM} \vdash \{mol_1 \, mol_2 \ldots \, mol_k\} \rightarrow \{mol'_1 \, mol'_2 \ldots mol'_l\} \]

2. **The Chemical Law.** Reactions can be performed freely within any solution:

   \[ \text{CHAM} \vdash sol \rightarrow sol' \]

   \[ \text{CHAM} \vdash sol \uplus sol'' \rightarrow sol' \uplus sol'' \]

3. **The Membrane Law.** A subsolution can evolve freely in any solution context $\{\text{ctx}[]\}$:

   \[ \text{CHAM} \vdash sol \rightarrow sol' \]

   \[ \text{CHAM} \vdash \{\text{ctx}[sol]\} \rightarrow \{\text{ctx}[sol']\} \]

4. **The Airlock Law.**

   \[ \text{CHAM} \vdash \{mol\} \uplus sol \leftrightarrow \{mol \triangleleft sol\} \]

   Note the unusual fact that $m_1 m_2 \ldots m_k \rightarrow m'_1 m'_2 \ldots m'_l$ being a rule in CHAM does not imply that $\text{CHAM} \vdash m_1 m_2 \ldots m_k \rightarrow m'_1 m'_2 \ldots m'_l$. Indeed, the CHAM rules are regarded as descriptors of changes that can take place in solutions and only in solutions, while CHAM sequents are incarnations of those otherwise purely abstract rules. What may be confusing is that the same descriptors of changes that can take place in solutions and only in solutions, while CHAM sequents apply also when $k$ and $l$ (the numbers of molecules in the left-hand and right-hand sides of the CHAM rule) happen to be 1 and $m_1$ and $m'_1$ happen to be solutions that contain no meta-variables. The two $\rightarrow$ arrows, namely the one in CHAM rules and the one in CHAM sequents, ought to be different symbols; however, we adhere to the conventional CHAM notation which uses the same symbol for both. Moreover, when the CHAM is clear from context, we also follow the conventional notation and drop it from sequents, that is, we write $sol \rightarrow sol'$ instead of $\text{CHAM} \vdash sol \rightarrow sol'$.

---

To avoid inventing new names, it is common to use “CHAM” both as an abbreviation for “the chemical abstract machine” and as a name of an arbitrary but fixed chemical abstract machine.
While we admit that these conventions may sometimes be confusing, in that \( sol \to sol' \) can be a rule or a sequent or even both, we hope that the context makes it clear which one is meant.

The Reaction Law says that CHAM rules can only apply in solutions (wrapped by a membrane), and not arbitrarily wherever they match. The Chemical Law says that once a reaction take place in a certain solution, it can take place in any other larger solution. In other words, the fact that a solution has more molecules than required by the rule does not prohibit the rule from applying. The Reaction and the Chemical laws together say that CHAM rules can apply inside any solutions having some molecules that match the left-hand side of the CHAM rule. An interesting case is when the left-hand-side term of the CHAM rule has only one molecule, i.e., when \( k = 1 \), because the CHAM rule is still allowed to only apply within a solution; it cannot apply in other places where the left-hand side happens to match.

The Membrane Law says that reactions can take place in any solution context. Indeed, \( \{\text{ctx}[sol]\} \) says that the solution \( sol \) (which is wrapped in a membrane) appears somewhere, anywhere, inside a solution context \( \{\text{ctx}[\square]\} \). Here \( \text{ctx} \) can be any bag-of-molecule context, and we write \( \text{ctx}[\square] \) to highlight the fact that it is a context with a hole \( \square \). By wrapping \( \text{ctx}[\square] \) in a membrane we enforce a solution context. This rule also suggests that, at any given moment, the global term to rewrite using the CHAM rules should be a solution. Indeed, the CHAM rewriting process gets stuck as soon as the term becomes a proper molecule (not a solution), because the Membrane Law cannot apply.

The Airlock Law is reversible (i.e., it comprises two rewrite rules, one from left-to-right and one from right-to-left) and it allows to extract a molecule from a solution, putting the rest of the solution within a membrane. Using this law one can, for example, rewrite a solution \( \{\text{mol}_1 \; \text{mol}_2 \; \ldots \; \text{mol}_k\} \) into \( \{\text{mol}_1 \triangleleft \{\text{mol}_2 \; \ldots \; \text{mol}_k\}\} \). The advantage of doing so is that one can now match the molecule \( \text{mol}_1 \) within other rules. Indeed, recall that sub-solutions that appear in rules cannot specify any particular molecule term among the rest of the solution, unless the solution contains precisely that molecule. Since \( \text{mol}_1 \triangleleft \{\text{mol}_2 \; \ldots \; \text{mol}_k\} \) is a molecule, \( \{\text{mol}_1 \triangleleft \{\text{mol}_2 \; \ldots \; \text{mol}_k\}\} \) can match molecule terms of the form \( \{m \triangleleft s\} \) appearing in CHAM rules, this way one effectively matching (and possibly modifying) the molecule \( \text{mol}_1 \) via the specific CHAM rules. The Airlock Law is the only means provided by the CHAM to extract or put molecules in a solution.

Note that the four laws above are not claimed to define the CHAM rewriting; they are only properties that the CHAM rewriting should satisfy. In particular, these laws do not capture the concurrency potential of the CHAM.

**Definition 19.** The four laws above give us a proof system for CHAM sequents. As usual, if we write \( \text{CHAM} \vdash sol \to sol' \) in isolation we mean that it is derivable. Also as usual, we let \( \to^* \) denote the reflexive and transitive closure of \( \to \), that is, \( \text{CHAM} \vdash sol \to^* sol' \) if and only if \( sol = sol' \) or there is some \( sol'' \) such that \( \text{CHAM} \vdash sol \to sol'' \) and \( \text{CHAM} \vdash sol'' \to^* sol' \). Finally, we write \( \text{CHAM} \vdash sol \iff sol' \) as a shorthand for the two sequents \( \text{CHAM} \vdash sol \to sol' \) and \( \text{CHAM} \vdash sol' \to sol \), and we say that it is derivable if and only if the two sequents are derivable.

**Exercise 83.** For any CHAM, any molecules \( \text{mol}_1, \ldots, \text{mol}_k \), and any \( 1 \leq i \leq k \), the sequents

\[
\text{CHAM} \vdash \{\text{mol}_1 \ldots \text{mol}_k\} \iff \{\text{mol}_1 \triangleright \{\text{mol}_2 \ldots \text{mol}_i\} \; \text{mol}_{i+1} \ldots \text{mol}_k\}
\]

are derivable, where if \( i = 1 \) then the bag \( \text{mol}_2 \ldots \text{mol}_i \) is the empty bag.

None of the two sequents in Definition 19 captures the underlying concurrent computation of the CHAM. Indeed, \( \text{CHAM} \vdash sol \to sol' \) says that one and only one reaction takes place somewhere in
sol, while CHAM $\rightarrow\text{sol} \rightarrow^* \text{sol}'$ says that arbitrarily many steps take place, including ones which can be done concurrently but also ones which can only take place sequentially. Therefore, we can think of the four laws above, and implicitly of the sequents CHAM $\rightarrow\text{sol} \rightarrow \text{sol}'$ and CHAM $\rightarrow\text{sol} \rightarrow^* \text{sol}'$, as expressing the “descriptive” capability of the CHAM: what is possible and what is not possible to compute using the CHAM, and not how it operates. We argue that it is still suggestive to think of CHAM reactions as taking place concurrently whenever they do not involve the same molecules, even though this notion is not formalized here. We are actually not aware of any works except this book that formalize the CHAM concurrency: one can find a representation of CHAM rewriting into K rewriting in Section 9.6 which allows the CHAM to “borrow” K’s concurrent rewriting.

A common source of misunderstanding the CHAM is to wrongly think of CHAM rules as ordinary rewriting rules modulo the associativity, commutativity and identity of the molecule grouping (inside a solution) operation. The major distinction between CHAM rules and such rewrite rules is that the former only apply within solutions (which are wrapped by membranes) no matter whether the rule contains one or more molecules in its left-hand or right-hand terms, while the latter apply anywhere they match. For example, supposing that one extends the syntax of molecules with the syntax of IMP in Section 3.1.1 and one adds a CHAM rule $m+0 \rightarrow m$, then one can rewrite the solution $\{3+0\}/7$ to solution $\{3\}/7$, but one cannot rewrite the molecule $5/(3+0)$ to molecule $5/3$ regardless of what context it is in, because $3+0$ is not in a solution. One cannot even rewrite the isolated (i.e., not in a solution context) term $3+0$ to $3$ in CHAM, for the same reason.

Classification of CHAM Rules

The rules of a CHAM are typically partitioned into three intuitive categories, namely heating, cooling and reaction rules, though there are no formal requirements imposing a rule to be into one category or another. Moreover, the same laws discussed above apply the same way to all categories of rules, and the same restrictions preventing multiset matching apply to all of them.

- **Heating** rules, distinguished by using the relation symbol $\rightarrow$ instead of $\rightarrow$, are used to structurally rearrange the solution so that reactions can take place.

- **Cooling** rules, distinguished by using the relation symbol $\rightarrow$ instead of $\rightarrow$, are used after reactions take place to structurally rearrange the solution back into a convenient form, including to remove useless molecules or parts of them.

- **Reaction** rules, which capture the intended computational steps and use the conventional rewrite symbol $\rightarrow$, are used to evolve the solution in an irreversible way.

The heating and cooling rules can typically be paired, with each heating rule $l \rightarrow r$ having a symmetric cooling rule $l \rightarrow r$, so that we can view them as a single bidirectional heating/cooling rule. The CHAM notation for writing such heating/cooling rules is the following:

$$l \equiv r$$

In particular, it makes sense to regard the airlock axiom as an example of such a heating/cooling bidirectional rule, that is,

$$\{m_1 \ m_2 \ldots \ m_k\} \equiv \{m_1 \triangleleft \{m_2 \ldots \ m_k\}\}$$

164
where $m_1, m_2, \ldots, m_k$ are molecule meta-variables. The intuition here is that we can heat the solution until $m_1$ is extracted in an airlock, or we can cool it down in which case the airlock $m_1$ is diffused within the solution. However, we need to assume one such rule for each $k > 0$.

As one may expect, the reaction rules are the heart of the Cham and properly correspond to state transitions. The heating and cooling rules express structural rearrangements, so that the reaction rules can match and apply. In other words, we can view the reaction rules as being applied modulo the heating and cooling rules. We are going to suggestively use the notation $\text{CHAM} \vdash \text{sol} \rightarrow \text{sol}'$, respectively $\text{CHAM} \vdash \text{sol} \rightarrow^* \text{sol}'$ whenever the rewrite step taking sol to sol' is a heating rule, respectively a cooling rule. Similarly, we may use the notations $\text{CHAM} \vdash \text{sol} \rightarrow^* \text{sol}'$ and $\text{CHAM} \vdash \text{sol} \rightarrow^* \text{sol}'$ for the corresponding reflexive/transitive closures. Also, to emphasize the fact that there is only one reaction rule applied, we take the freedom to (admittedly ambiguously) write $\text{CHAM} \vdash \text{sol} \rightarrow \text{sol}'$ instead of $\text{CHAM} \vdash \text{sol}(\rightarrow \cup \rightarrow \rightarrow)^* \text{sol}'$ whenever all the involved rules but one are heating or cooling rules.

The CHAM of IMP

We next show how to give IMP a CHAM semantics. CHAM is particularly well-suited to giving semantics to concurrent distributed calculi and languages, yielding considerably simpler definitions than those afforded by SOS. Since IMP is sequential, it cannot take full advantage of the CHAM’s true concurrency capabilities; the multi-threaded IMP++ language discussed in Section 3.8 will make slightly better use of CHAM's capabilities. Nevertheless, some of CHAM's capabilities turn out to be useful even in this sequential language application, others turn out to be deceiving.

Our CHAM semantics for IMP below follows in principle the reduction semantics with evaluation contexts definition discussed in Section 3.5.1. One can formally show that a step performed using reduction under evaluation contexts is equivalent to a suite of heating steps, followed by one reaction step, followed by a suite of cooling steps.

The CHAM defined below is just one possible way to give IMP a CHAM semantics. CHAM, like rewriting, is a general framework which does not impose upon its users any particular definitional style. In our case, we chose to conceptually distinguish two types of molecules; we say “conceptually” because, for simplicity, we prefer to define only one Molecule syntactic category in our CHAM:

- **Syntactic molecules**, which include all the syntax of IMP in Section 3.1.1 plus all the syntax of its evaluation contexts in Section 3.5.1 plus a mechanism to flatten evaluation contexts; again, for simplicity, we prefer not to include a distinct type of molecule for each distinct syntactic category of IMP.

- **State molecules**, which are pairs $x \leftrightarrow i$, where $x \in \text{Id}$ and $i \in \text{Int}$.

For clarity, we prefer to keep the syntactic and the state molecules in separate solutions. More precisely, we work with top-level configurations which are solutions of the form

$$\{\{\text{Syntax}\}\;\{\text{State}\}\}$$

Syntax and State are solutions containing syntactic and state molecules, respectively. For example,

$$\{\{x := (3/ (x + 2))\}\;\{x \leftrightarrow 1\; y \leftrightarrow 0\}\}$$

is a CHAM configuration containing the statement $x := (3/ (x + 2))$ and state $x \leftrightarrow 1, y \leftrightarrow 0$. 165
The state molecules and implicitly the state solution are straightforward. State molecules are not nested and state solutions are simply multisets of molecules of the form \( x \mapsto i \). The CHAM does not allow us to impose constraints on solutions, such as that the molecules inside the state solution indeed define a partial function and not some arbitrary relation (e.g., that there is at most one molecule \( x \mapsto i \) for each \( x \in \text{Id} \)). Instead, the state solution will be used in such a way that the original state solution will embed a proper partial function and each rule will preserve this property of it. For example, the CHAM rule for variable assignment, say when assigning integer \( i \) to variable \( x \), will match the state molecule as \( \langle x \mapsto i \rangle \) and will rewrite it to \( \langle x \mapsto i \rangle \).

The top level syntactic solution holds the current program or fragment of program that is still left to be processed. It is not immediately clear how the syntactic solution should be represented in order to be able to give IMP a CHAM semantics. The challenge here is that the IMP language constructs have evaluation strategies and the subterms that need to be next processed can be arbitrarily deep into the program or fragment of program, such as the framed \( x := (3 / ((x + 2)) \). If the CHAM allowed conditional rules, then we could have followed an approach similar to that of SOS described in Section 3.5, reducing the semantics of each language construct to that of its subexpressions or substatements. Similarly, if the CHAM allowed matching using evaluation contexts, then we could have followed a reduction semantics with evaluation contexts approach like the one in Section 3.5.1 which uses only unconditional rules. Unfortunately, the CHAM allows neither conditional rules nor evaluation contexts in matching, so a different approach is needed.

Failed attempts to represent syntax. A natural approach to represent the syntax of a programming language in CHAM may be to try to use CHAM’s heating/cooling and molecule/solution nesting mechanisms to decompose syntax unambiguously in such a way that the redex (i.e., the subterm which can be potentially reduced next; see Section 3.5) appears as a molecule in the top syntactic solution. That is, if \( p \rightarrow c[t] \) is a program or fragment of program which can be decomposed in evaluation context \( c \) and redex \( t \), then one may attempt to represent it as a solution of the form \( \langle t \rightarrow \gamma_c \rangle \), where \( \gamma_c \) is some CHAM representation of the evaluation context \( c \). If this worked, then we could use an airlock operation to isolate that redex from the rest of the syntactic solution, i.e. \( \{p\} \leftarrow \{t \rightarrow \gamma_c \} \leftarrow \{t \leftarrow \gamma_c \} \), and thus have it at the same level with the state solution in the configuration solution; this would allow to have rules that match both a syntactic molecule and a state molecule (after an airlock operation is applied on the state solution as well) in the same rule, as needed for the semantics of lookup and assignment. In our example above, we would obtain

\[
\langle x := (3 / ((x + 2)) \rangle \rightarrow \{x \mapsto 1, y \mapsto 0\}\rightarrow \{x \mapsto i < \gamma_x : = (3 / ((x + 2)) \rangle \rightarrow \{x \mapsto 1 < \} \rightarrow \{y \mapsto 0\}\}
\]

and the latter could be rewritten with a natural CHAM reaction rule for variable lookup such as

\[
\{x \mapsto i < \sigma\} \rightarrow \{i < c\} \rightarrow \{x \mapsto i < \sigma\}
\]

Unfortunately, there seems to be no way to achieve such a desirable CHAM representation of syntax. If the CHAM

Consider, again, the statement \( x := (3 / ((x + 2)) \). A naive approach to represent this statement term as a syntactic solution (by means of appropriate heating/cooling rules) is to flatten it into its redex, namely \( x \), and into all its atomic evaluation subcontexts, that is, to represent it as the following solution:

\[
\{x \ (\square + 2) \ (3 / \square) \ (x := \square)\}
\]
With these modified rules, one may now think that one can heat and cool syntax unambiguously:

\[ x := a \quad a < \{x := \square\} \]
\[ a_1 + a_2 \quad a_1 < \{\square + a_2\} \]
\[ a_1 + a_2 \quad a_2 < \{a_1 + \square\} \]

With such rules, one can now heat or cool syntax as desired, for example:

\[ \{x := (3/(x+2))\} \Rightarrow \{(3/(x+2)) < \{x := \square\}\} \quad \text{(Reaction)} \]
\[ \Rightarrow \{(3/(x+2)) \quad (x := \square)\} \quad \text{(Airlock)} \]
\[ \Rightarrow \{(x+2) \quad (3/\square) \quad (x := \square)\} \quad \text{(Reaction, Chemical, Airlock)} \]
\[ \Rightarrow \{x \quad (\square + 2) \quad (3/\square) \quad (x := \square)\} \quad \text{(Reaction, Chemical, Airlock)} \]

Unfortunately this naive approach is ambiguous, because it cannot distinguish the above from the representation of, say, \(x := ((3/\times + 2)\). The problem here is that the precise structure of the evaluation context is “lost in translation”, so the approach above does not work.

Let us attempt a second approach, namely to guarantee that there is precisely one hole \(\square\) molecule in each syntactic subsolution by using the molecule/solution nesting mechanism available in CHAM. More precisely, let us try to unambiguously represent the statements \(x := (3/(x+2))\) and \(x := ((3/\times + 2)\) as the following two distinct syntactic solutions:

\[ \{x \quad ((\square + 2) \quad (3/\square) \quad (x := \square))\} \]
\[ \{x \quad (3/\square) \quad (\square + 2) \quad (x := \square)\} \]

To achieve this, we modify the heating/cooling rules above as follows:

\[ (x := a) < c \quad a < \{(x := \square) < c\} \]
\[ (a_1 + a_2) < c \quad a_1 < \{(\square + a_2) < c\} \]
\[ (a_1 + a_2) < c \quad a_2 < \{(a_1 + \square) < c\} \]

With these modified rules, one may now think that one can heat and cool syntax unambiguously:

\[ \{x := (3/(x+2))\} \Rightarrow \{(x := (3/(x+2)) < \{\} \}\} \quad \text{(Airlock)} \]
\[ \Rightarrow \{(3/(x+2)) < \{(x := \square) < \{\} \}\} \quad \text{(Reaction)} \]
\[ \Rightarrow \{(3/(x+2)) < \{\} \quad (x := \square)\} \quad \text{(Airlock, Membrane)} \]
\[ \Rightarrow \{(x+2) < \{(3/\square) < \{x := \square\} \}\} \quad \text{(Reaction)} \]
\[ \Rightarrow \{(x+2) < \{(3/\square) \quad (x := \square)\} \}\} \quad \text{(Airlock, Membrane)} \]
\[ \Rightarrow \{x < \{(\square + 2) \quad (3/\square) \quad (x := \square)\}\}\} \quad \text{(Reaction)} \]
\[ \Rightarrow \{x < \{(\square + 2) \quad (3/\square) \quad (x := \square)\} \}\} \quad \text{(Airlock, Membrane)} \]
\[ \Rightarrow \{x \quad ((\square + 2) \quad (3/\square) \quad (x := \square))\} \quad \text{(Airlock)} \]

Unfortunately, the above is not the only way one can heat the solution in question. For example, the following is also a possible derivation, showing that these heating/cooling rules are still problematic:

\[ \{x := (3/(x+2))\} \Rightarrow \{(x := (3/(x+2)) < \{\} \}\} \quad \text{(Airlock)} \]
\[ \Rightarrow \{(3/(x+2)) < \{(x := \square) < \{\} \}\} \quad \text{(Reaction)} \]
\[ \Rightarrow \{(3/(x+2)) < \{\} \quad (x := \square)\} \quad \text{(Airlock, Membrane)} \]
\[ \Rightarrow \{(3/(x+2)) \quad (x := \square)\} \quad \text{(Airlock)} \]
\[ \Rightarrow \{(x+2) \quad (3/\square) \quad (x := \square)\} \quad \text{(All four laws)} \]
\[ \Rightarrow \{x \quad (\square + 2) \quad (3/\square) \quad (x := \square)\} \quad \text{(All four laws)} \]
Indeed, one can similarly show that
\[
\{x := ((3/x)+2)\} \Rightarrow \{x \div (\square+2) \div 3 \div x := \square\}\}
\]

Therefore, this second syntax representation attempt is also ambiguous.

We claim that it is impossible to devise heating/cooling rules in CHAM and representations \(\gamma\) of evaluation contexts with the property that
\[
\{c[t]\} \Rightarrow \{t \gamma\} \quad \text{or, equivalently,} \quad \{c[t]\} \Rightarrow \{t \Downarrow \{\gamma\}\}
\]
for any term \(t\) and any appropriate evaluation context \(c\). Indeed, if that was possible, then the following derivation could be possible:

\[
\{x := (3/(x+2))\} \Rightarrow \{(3/(x+2)) \gamma_x := \square\} \quad \text{(hypothesis)}
\]
\[
\Rightarrow \{(x+2) \gamma_{3/\square} \gamma_x := \square\} \quad \text{(hypothesis, Chemical)}
\]
\[
\Rightarrow \{x \gamma_{3+2} \gamma_{3/\square} \gamma_x := \square\} \quad \text{(hypothesis, Chemical)}
\]
\[
\Rightarrow \{(3/x) \gamma_{3+2} \gamma_x := \square\} \quad \text{(hypothesis, Chemical)}
\]
\[
\Rightarrow \{((3/x)+2) \gamma_x := \square\} \quad \text{(hypothesis, Chemical)}
\]
\[
\Rightarrow \{x := ((3/x)+2)\} \quad \text{(hypothesis)}
\]

This general impossibility result explains why both our representation attempts above failed, as well as why many other similar attempts are also expected to fail.

The morale of the exercise above is that one should be very careful when using CHAM’s airlock, because in combination with the other CHAM laws it can yield unexpected behaviors. In particular, the Chemical Law makes it impossible to state that a term matches the entire contents of a solution molecule, so one should not rely on the fact that all the remaining contents of a solution is in the membrane following the airlock. In our heating/cooling rules above, for example

\[
(x := a) \Downarrow c \Rightarrow a \Downarrow \{\{x := \square\} \Downarrow c\}\}
\]
\[
(a_1 + a_2) \Downarrow c \Rightarrow a_1 \Downarrow \{\{(\square+a_2) \Downarrow c\}\}
\]
\[
(a_1 + a_2) \Downarrow c \Rightarrow a_2 \Downarrow \{\{(a_1 + \square) \Downarrow c\}\}
\]

our intuition that \(c\) matches \textit{all} the evaluation context solution representation was wrong precisely for that reason. Indeed, it can just as well match a solution representation of a subcontext, which is why we got the “unexpected” derivation.

**Correct representation of syntax.** We next discuss an approach to representing syntax which is \textit{not} based on CHAM’s existing solution/membrane mechanism. We borrow from K (see Chapter 3) the idea of flattening syntax in an explicit list of computational tasks. Like in K, we use the symbol \(\sim\), read “then” or “followed by”, to separate such computational tasks; to avoid writing parentheses, we here assume that \(\sim\) is right-associative and binds less tightly than any other construct. For example, the term \(x := (3/(x+2))\) gets represented as the list term
\[
x \sim \square + 2 \sim 3/\square \sim x := \square \sim \square
\]

which reads “process \(x\), followed by adding 2 to it, followed by dividing 3 by the result, followed by assigning the obtained result to \(x\), which is the final task”. Figure 3.41 shows all the heating/cooling rules that we associate to the various evaluation strategies of the IMP language constructs. These
The syntactic solution will contain only one syntactic molecule at any given moment, with no mechanically derived from the rules of the reduction semantics with evaluation contexts of IMP language construct. Like the heating/cooling rules in Figure 3.41, these rules are also almost contexts for the computational tasks) and an evaluation context (represented flattened as the rest of the list). In fact, the syntactic term into any of its possible splits into a redex (the top of the resulting list of etc.), as we do in K (see Section 5). The heating/cooling rules in Figure 3.41 effectively decompose tasks in the syntactic molecule, \( c \), language construct evaluation strategies need to mention the remaining list of computational subsolutions, which is the reason why the heating/cooling rules in Figure 3.41 that correspond to \( s \) not correspond to the evaluation strategy of some evaluation construct is \( s \Rightarrow s \Rightarrow \square \). Its role is to initiate the decomposition process whenever an unheated statement is detected in the syntax solution. According to CHAM’s laws, these rules can only apply in solutions, so we can derive

\[
\{ x := 1 ; x := (3 / (x + 2)) \} \Rightarrow \{ x := 1 \Rightarrow \square ; x := (3 / (x + 2)) \Rightarrow \square \}
\]

but there is no way to derive, for example,

\[
\{ x := 1 ; x := (3 / (x + 2)) \} \Rightarrow^* \{ x := 1 ; (x \Rightarrow \square + 2 \Rightarrow 3 / \square \Rightarrow x := \square \Rightarrow \square) \}
\]

The syntactic solution will contain only one syntactic molecule at any given moment, with no subsolutions, which is the reason why the heating/cooling rules in Figure 3.41 correspond to language construct evaluation strategies need to mention the remaining of the list of computational tasks in the syntactic molecule, \( c \), instead of just the “interesting” part (e.g., \( a_1 + a_2 \Rightarrow a_1 \Rightarrow \square + a_2 \), etc.), as we do in K (see Section 5). The heating/cooling rules in Figure 3.41 effectively decompose the syntactic term into any of its possible splits into a redex (the top of the resulting list of computational tasks) and an evaluation context (represented flattened as the rest of the list). In fact, these heating/cooling rules have been almost mechanically derived from the syntax of evaluation contexts for the IMP language constructs in Section 3.5.1 (see Figure 3.27).

Figure 3.42 shows the remaining CHAM rules of IMP, giving the actual semantics of each language construct. Like the heating/cooling rules in Figure 3.41, these rules are also almost mechanically derived from the rules of the reduction semantics with evaluation contexts of IMP in Section 3.5.1 (see Figure 3.28), with the following notable differences:

- Each rule needs to mention the remaining list of computational tasks, \( c \), for the same reason the heating/cooling rules in Figure 3.41 need to mention it (which is explained above).

- There is no equivalent of the characteristic rule of reduction semantics with evaluation contexts. The Membrane Law looks somehow similar, but we cannot take advantage of that because we were not able to use the inherent airlock mechanism of the CHAM to represent syntax (see the failed attempts to represent syntax above).
\[ i_1 + i_2 \sim c \rightarrow i_1 + \text{int} \, i_2 \sim c \]
\[ i_1 / i_2 \sim c \rightarrow i_1 / \text{num} \, i_2 \sim c \quad \text{when } i_2 \neq 0 \]
\[ i_1 \leq \text{int} \, i_2 \sim c \]
\[ \text{not true} \sim c \rightarrow \text{false} \sim c \]
\[ \text{true and } b_2 \sim c \rightarrow b_2 \sim c \]
\[ \text{false and } b_2 \sim c \rightarrow \text{false} \sim c \]
\[ \{ x := i \sim c \} \{ x \mapsto j \sigma \} \rightarrow \{ \text{skip} \sim c \} \{ x \mapsto i \sigma \} \]
\[ \text{skip} ; s_2 \sim c \rightarrow s_2 \sim c \]
\[ \text{if true then } s_1 \text{ else } s_2 \sim c \rightarrow s_1 \sim c \]
\[ \text{if false then } s_1 \text{ else } s_2 \sim c \rightarrow s_2 \sim c \]
\[ \text{while } b \text{ do } s \sim c \rightarrow \text{if } b \text{ then } (s \; \text{while } b \; s) \text{ else } \text{skip} \sim c \]
\[ \text{vars } x l \; s \rightarrow \{ s \} \{ x l \leftrightarrow 0 \} \]
\[ (x, x l) \mapsto i \rightarrow x \mapsto i \triangleright \{ x l \mapsto i \} \]

Figure 3.42: CHAM(IMP): The CHAM of IMP, obtained by adding to the heating/cooling rules in Figure 3.41 the semantic rules for IMP plus the heating rule for state initialization above.

- The state is organized as a solution using CHAM’s airlock mechanism, instead of just imported as an “external” data-structure as we did in our previous semantics. We did so because the state data-structure that we used in our previous semantics was a finite-domain partial function (see Section 3.1.2), which was represented as a set of pairs (Section 2.1.2), and it is quite natural to replace any set structures by the inherent CHAM solution mechanism.

Exercise 84. Modify the CHAM semantics of IMP in Figure 3.42 to use a state data-structure as we did in the previous semantics instead of representing the state as a solution of binding molecules.

Figure 3.43 shows a possible execution of IMP’s CHAM defined above, mentioning at each step which of CHAM’s laws have been applied. Note that the final configuration contains two subsolutions, one for the syntax and one for the state. Since the syntactic subsolution in the final configuration solution is expected to always contain only \text{skip}, one can safely eliminated it.

Exercise 85. Add a “cleanup” (cooling) rule to the CHAM semantics of IMP in Figure 3.42 to remove the useless syntactic subsolution when the computation is terminated. The resulting solution should only contain a state (i.e., it should have the form \{ \sigma \}, and not \{ \{ \sigma \} \} or \{ \{ \cdot \} \{ \sigma \} \}).

Exercise 86. Modify the CHAM semantics of IMP in Figures 3.41 and 3.42 so that / short-circuits when the numerator evaluates to 0.

Exercise 87. Modify the CHAM semantics of IMP in Figures 3.41 and 3.42 so that conjunction is non-deterministically strict in both its arguments.

CHAM in Rewriting Logic

As explained above, CHAM rewriting cannot be immediately captured as ordinary rewriting modulo solution multiset axioms such as associativity, commutativity and identity. The distinction between
will stay during the entire rewriting process, and so the Membrane Law is also naturally captured

where the only difference between the original CHAM terms

is not a solution), then so it will stay during the entire rewriting logic’s rewriting while the CHAM

that rewrite solutions into solutions. Thus, if the original term to rewrite is a solution, then so it

in the latter, and where

into corresponding rewriting logic rules of the form

solution, because the CHAM laws restrict the applications of such a rule only in solutions while

ordinary rewriting allows such rules to apply everywhere. To solve this problem, we wrap each rule

in a solution context, that is, we translate CHAM rules of the form

into corresponding rewriting logic rules of the form

where the only difference between the original CHAM terms $m_1, m_2, \ldots, m_k, m'_1, m'_2, \ldots, m'_l$ and

their algebraic variants $\overline{m_1}, \overline{m_2}, \ldots, \overline{m_k}, \overline{m'_1}, \overline{m'_2}, \ldots, \overline{m'_l}$ is that the meta-variables appearing in the

former (recall that CHAM rules are rule schemata) are turned into variables of corresponding sorts

in the latter, and where $Ms$ is a variable of sort $\text{Bag}\{\text{Molecule}\}$ that does not appear anywhere

else in $\overline{m_1}, \overline{m_2}, \ldots, \overline{m_k}, \overline{m'_1}, \overline{m'_2}, \ldots, \overline{m'_l}$.

With this representation of CHAM rules into rewriting logic rules, it is obvious that rewriting

logic’s rewriting captures both the Reaction Law and the Chemical Law of the CHAM. What is less

obvious is that it also captures the Membrane Law. Indeed, note that the Membrane Law allows

rewrites to take place only when the global term is a solution, while rewriting logic allows rewrites
to take place anywhere. However, the rewriting logic rule representation above generates only rules

that rewrite solutions into solutions. Thus, if the original term to rewrite is a solution, then so it

will stay during the entire rewriting process, and so the Membrane Law is also naturally captured

by rewriting logic derivations. However, if the original term to rewrite is a proper molecule (which

is not a solution), then so it will stay during the entire rewriting logic’s rewriting while the CHAM

will not reduce it at all. Still it is important to understand that in this case the corresponding

Figure 3.43: An execution of IMP’s CHAM.

the two arises essentially when a CHAM rule involves only one top-level molecule which is not a

solution, because the CHAM laws restrict the applications of such a rule only in solutions while

ordinary rewriting allows such rules to apply everywhere. To solve this problem, we wrap each rule

in a solution context, that is, we translate CHAM rules of the form

$m_1 m_2 \ldots m_k \rightarrow m'_1 m'_2 \ldots m'_l$

into corresponding rewriting logic rules of the form

$\overline{m_1} \overline{m_2} \ldots \overline{m_k} \overline{Ms} \rightarrow \overline{m'_1} \overline{m'_2} \ldots \overline{m'_l} \overline{Ms}$

where $\overline{m_1}, \overline{m_2}, \ldots, \overline{m_k}, \overline{m'_1}, \overline{m'_2}, \ldots, \overline{m'_l}$ is that the meta-variables appearing in the

former (recall that CHAM rules are rule schemata) are turned into variables of corresponding sorts

in the latter, and where $Ms$ is a variable of sort $\text{Bag}\{\text{Molecule}\}$ that does not appear anywhere

else in $\overline{m_1}, \overline{m_2}, \ldots, \overline{m_k}, \overline{m'_1}, \overline{m'_2}, \ldots, \overline{m'_l}$.

With this representation of CHAM rules into rewriting logic rules, it is obvious that rewriting

logic’s rewriting captures both the Reaction Law and the Chemical Law of the CHAM. What is less

obvious is that it also captures the Membrane Law. Indeed, note that the Membrane Law allows

rewrites to take place only when the global term is a solution, while rewriting logic allows rewrites
to take place anywhere. However, the rewriting logic rule representation above generates only rules

that rewrite solutions into solutions. Thus, if the original term to rewrite is a solution, then so it

will stay during the entire rewriting process, and so the Membrane Law is also naturally captured

by rewriting logic derivations. However, if the original term to rewrite is a proper molecule (which

is not a solution), then so it will stay during the entire rewriting logic’s rewriting while the CHAM

will not reduce it at all. Still it is important to understand that in this case the corresponding

171
rewriting logic theory can perform rewrite steps (in subsolutions of the original term) which are not possible under the CHAM, in particular that it may lead to non-termination in situations where the CHAM is essentially stuck. To reconcile this inherent difference between the CHAM and rewriting logic, we make the reasonable assumption that the original terms to rewrite can only be solutions. Note that the CHAM sequents in Definition 19 already assume that one only derives solution terms.

The only CHAM law which has not been addressed above is the Airlock Law. Rewriting logic has no builtin construct resembling CHAM’s airlock, but its multiset matching is powerful enough to allow us to capture the airlock’s behavior through rewrite rules. One possibility is to regard the airlock operation like any other molecular construct. Indeed, from a rewriting logic perspective, the Airlock Law says that any molecule inside a solution can be matched and put into an airlock next to the remaining solution wrapped into a membrane, and this process is reversible. This behavior can be achieved through the following two (opposite) rewrite logic rules, where $M$ is a molecule variable and $Ms$ is a bag-of-molecules variable:

$$\{M Ms\} \rightarrow \{M \triangleright \{Ms\}\}$$

$$\{M \triangleright \{Ms\}\} \rightarrow \{M Ms\}$$

Another possibility to capture airlock’s behavior in rewriting logic is to attempt to eliminate it completely and replace it with matching modulo multiset axioms. While this appears to be possible in many concrete situations, we are however not aware of any general solution to do so systematically for any CHAM. The question is whether the elimination of the airlock is indeed safe, in the sense that the resulting rewriting logic theory does not lose any of the original CHAM’s behaviors. One may think that thanks to the restricted form of CHAM’s rules, the answer is immediately positive. Indeed, since the CHAM disallows any other constructs for solutions except its builtin membrane operation (a CHAM can only add new syntactic constructs for molecules, but not for solutions) and since solution subterms can either contain only one molecule or otherwise be meta-variables (to avoid multiset matching), we can conclude that in any CHAM rule, a subterm containing an airlock operation at its top can only be of the form $m \triangleright \{m’\}$ or of the form $m \triangleright s$ with $s$ a meta-variable. Both these cases can be uniformly captured as subterms of the form $\overline{m} \triangleright \{ms\}$ with $ms$ a term of sort $\text{Bag}\{\text{Molecule}\}$ in rewriting logic, the former by taking $k = 1$ and $ms = m’$ and the latter by replacing the metavariable $s$ with a term of the form $\{Ms\}$ everywhere in the rule, where $Ms$ is a fresh variable of sort $\text{Bag}\{\text{Molecule}\}$. Unfortunately, it is not clear how we can eliminate the airlock from subterms of the form $\overline{m} \triangleright \{ms\}$. If such terms appear in a solution or at the top of the rule, then one can replace them by their corresponding bag-of-molecule terms $\overline{m} ms$. However, if they appear in a proper molecule context (i.e., not in a solution context), then they cannot be replaced by $\overline{m} ms$ (first, we would get a parsing error by placing a bag-of-molecule term in a molecule place; second, reactions cannot take place in $ms$ anymore, because it is not surrounded by a membrane). We cannot replace $\overline{m} \triangleright \{ms\}$ by $\overline{\overline{m} ms}$ either, because that would cause a double membrane when the thus modified airlock reaches a solution context. Therefore, we keep the airlock.

Putting all the above together, we can associate a rewriting logic theory to any CHAM as shown in Figure 3.44 for simplicity, we assumed that the CHAM has only one $\text{Molecule}$ syntactic category and, implicitly, only one corresponding $\text{Solution}$ syntactic category. In Figure 3.44 and elsewhere in this section, we use the notation $\text{left} \leftrightarrow \text{right}$ as a shorthand for two opposite rewrite rules, namely for both $\text{left} \rightarrow \text{right}$ and $\text{right} \rightarrow \text{left}$. The discussion above implies the following result:

**Theorem 10. (Embedding of the chemical abstract machine into rewriting logic)** If CHAM is a chemical abstract machine, sol and sol’ are two solutions, and $R_{\text{CHAM}}$ is the rewrite logic theory associated to CHAM as in Figure 3.44 then the following hold:
sorts:
   Molecule, Solution, Bag{Molecule}
subsorts:
   Solution < Molecule
   // One may also need to subsort to Molecule specific syntactic categories (Int, Bool, etc.)
operations:
   \( \langle \rangle \) : Bag\{Molecule\} \rightarrow Solution  // membrane operator
   \(-\triangleright\) : Molecule \times Solution \rightarrow Molecule  // airlock operator
   // One may also need to define specific syntactic constructs for Molecule (\(+\), \(-\triangleright\), etc.)
rules:
   // Add the following two generic (i.e., same for all CHAMs) airlock rewrite logic rules:
   \( \{M\} \leftrightarrow \{M \triangleright \{Ms\}\} \)  // M, Ms variables of sorts Molecule, Bag\{Molecule\}, resp.
   // For each specific CHAM rule \(m_1 m_2 \ldots m_k \rightarrow m'_1 m'_2 \ldots m'_l\) add a rewriting logic rule
   \( \{m_1 \ldots m_k Ms\} \rightarrow \{m'_1 \ldots m'_l Ms\} \)  // Ms variable of sort Bag\{Molecule\}
   // where \(\bar{m}\) replaces each meta-variable in \(m\) by a variable of corresponding sort.

Figure 3.44: Embedding of a chemical abstract machine into rewriting logic (CHAM \(\sim\) \(R_{CHAM}\)).

1. CHAM\(\sim\)sol \(\rightarrow\) sol’ if and only if \(R_{CHAM}\)\(\sim\)sol \(\rightarrow^{1}\) sol’;
2. CHAM\(\sim\)sol \(\rightarrow^{*}\) sol’ if and only if \(R_{CHAM}\)\(\sim\)sol \(\rightarrow^{*}\) sol’.

Therefore, one-step solution rewriting in \(R_{CHAM}\) corresponds precisely to one-step solution rewriting in the original CHAM and thus, one can use \(R_{CHAM}\) as a replacement for CHAM for any reduction purpose. Unfortunately, this translation of CHAM into rewriting logic does not allow us to “borrow” the latter’s concurrency to obtain the desired concurrent rewriting computational mechanism of the former. Indeed, the desired CHAM concurrency says that “different rule instances can apply concurrently in the same solution as far as they act on different molecules”. Unfortunately, the corresponding rewrite logic rule instances cannot apply concurrently according to rewriting logic’s semantics because both instances would match the entire solution, including the membrane (and rule instances which overlap cannot proceed concurrently in rewriting logic — see Section 2.7).

The CHAM of IMP in Rewriting Logic

Figure 3.45 shows the rewrite theory \(R_{CHAM(IMP)}\) obtained by applying the generic transformation procedure in Figure 3.44 to the CHAM of IMP discussed in this section and summarized in Figures 3.41 and 3.42. In addition to the generic CHAM syntax, as indicated in the comment under “subsorts” in Figure 3.44 we also subsort the “builtin” sorts of IMP, namely Int, Bool and Id, to Molecule. The “followed by” \(-\triangleright\) construct for molecules is necessary for defining the evaluation strategies of the various IMP language constructs as explained above; we believe that some similar operator is necessary when defining any programming language whose constructs have evaluation strategies because, as explained above, it appears that the CHAM airlock operator is not suitable for this task. For notational simplicity, we stick to our previous convention that \(-\triangleright\) is right associative and binds less tight than any other molecular construct. Finally, we add molecular constructs
sorts:
\[
Molecule, \ Solution, \ Bag\{Molecule\}
\] // generic CHAM sorts

subsorts:
\[
Solution < Molecule \quad \text{// generic CHAM subsort}
\]
\[
Int, \ Bool, \ Id < Molecule \quad \text{// additional IMP-specific syntactic categories}
\]

operations:
\[
\{\_\_\_\} : \text{Bag\{Molecule\}} \rightarrow \text{Solution} \quad \text{// generic membrane}
\]
\[
\_\_\_ : \text{Molecule} \times \text{Solution} \rightarrow \text{Molecule} \quad \text{// generic airlock}
\]
\[
\_\sim : \text{Molecule} \times \text{Molecule} \rightarrow \text{Molecule} \quad \text{// “followed by” operator, for evaluation strategies}
\]

// Plus all the IMP language constructs and evaluation contexts (all listed in Figure 3.27),
// collapsing all syntactic categories different from Int, Bool and Id into Molecule

rules:

// Airlock:
\[
\{M \ M_{r}\} \leftrightarrow \{M \leadsto \{M_{r}\}\}
\]

// Heating/cooling rules corresponding to the evaluation strategies of IMP’s constructs:
\[
\{(A_{1} + A_{2} \sim C) \ M_{r}\} \leftrightarrow \{(A_{1} \sim \Box + A_{2} \sim C) \ M_{r}\}
\]
\[
\{(A_{1} \sim \Box + A_{2} \sim C) \ M_{r}\} \leftrightarrow \{(A_{2} \sim A_{1} + \Box \sim C) \ M_{r}\}
\]
\[
\{(A_{1} / A_{2} \sim C) \ M_{r}\} \leftrightarrow \{(A_{2} \sim A_{1} / \Box \sim C) \ M_{r}\}
\]
\[
\{(A_{1} / A_{2} \sim C) \ M_{r}\} \leftrightarrow \{(A_{2} \sim A_{1} / \Box \sim C) \ M_{r}\}
\]
\[
\{(A_{1} \sim \Box \ll \ll A_{2} \sim C) \ M_{r}\} \leftrightarrow \{(A_{1} \sim \Box \ll \ll A_{2} \sim C) \ M_{r}\}
\]
\[
\{(I_{1} \ll A_{2} \sim C) \ M_{r}\} \leftrightarrow \{(A_{2} \sim I_{1} \ll \ll \ll C) \ M_{r}\}
\]
\[
\{(\text{not} B \sim C) \ M_{r}\} \leftrightarrow \{(B \sim \text{not} \Box \sim C) \ M_{r}\}
\]
\[
\{(B_{1} \sim B_{2} \sim C) \ M_{r}\} \leftrightarrow \{(B_{1} \sim \Box \sim \Box \sim C) \ M_{r}\}
\]
\[
\{(X = A \sim C) \ M_{r}\} \leftrightarrow \{(A \sim X = \Box \sim C) \ M_{r}\}
\]
\[
\{(S_{1} ; S_{2} \sim C) \ M_{r}\} \leftrightarrow \{(S_{1} \sim \Box ; S_{2} \sim C) \ M_{r}\}
\]
\[
\{S_{r} \ M_{r}\} \leftrightarrow \{(S \sim \Box) \ M_{r}\}
\]
\[
\{(\text{if} B \text{then} S_{1} \text{else} S_{2} \sim C) \ M_{r}\} \leftrightarrow \{(B \sim \text{if} \Box \sim S_{1} \text{else} S_{2} \sim C) \ M_{r}\}
\]

// Semantic rewrite rules corresponding to “reaction” computational steps
\[
\{(X \sim C) \rightarrow \{X \rightarrow I \sim \Box \sim C \ M_{r}\} \rightarrow \{(I_{1} \sim \Box \sim I_{2} \sim C) \ M_{r}\}
\]
\[
\{(I_{1} \sim I_{2} \sim C) \ M_{r}\} \rightarrow \{(I_{1} + \text{int} I_{2} \sim C) \ M_{r}\}
\]
\[
\{(I_{1} / I_{2} \sim C) \ M_{r}\} \rightarrow \{(I_{1} / \text{int} I_{2} \sim C) \ M_{r}\} \text{if} I_{2} \neq 0
\]
\[
\{(I_{1} \ll I_{2} \sim C) \ M_{r}\} \rightarrow \{(I_{1} \ll \text{int} I_{2} \sim C) \ M_{r}\}
\]
\[
\{(\text{not} \text{true} \sim C) \ M_{r}\} \rightarrow \{(\text{false} \sim C) \ M_{r}\}
\]
\[
\{(\text{not} \text{false} \sim C) \ M_{r}\} \rightarrow \{(\text{true} \sim C) \ M_{r}\}
\]
\[
\{(\text{true} \sim B_{2} \sim C) \ M_{r}\} \rightarrow \{(B_{2} \sim C) \ M_{r}\}
\]
\[
\{(\text{false} \sim B_{2} \sim C) \ M_{r}\} \rightarrow \{(\text{false} \sim C) \ M_{r}\}
\]
\[
\{(X := I \sim C) \rightarrow \{X \rightarrow J \sim \Box \sim C \ M_{r}\} \rightarrow \{(\text{skip} \sim C) \rightarrow \{X \rightarrow I \sim \Box \sim C \ M_{r}\}
\]
\[
\{(\text{skip} ; S_{2} \sim C) \ M_{r}\} \rightarrow \{(S_{2} \sim C) \ M_{r}\}
\]
\[
\{(\text{if} \text{true} \text{then} S_{1} \text{else} S_{2} \sim C) \ M_{r}\} \rightarrow \{(S_{1} \sim C) \ M_{r}\}
\]
\[
\{(\text{if} \text{false} \text{then} S_{1} \text{else} S_{2} \sim C) \ M_{r}\} \rightarrow \{(S_{2} \sim C) \ M_{r}\}
\]
\[
\{(\text{while} B \text{do} S \sim C) \ M_{r}\} \rightarrow \{(S_{2} \sim C) \ M_{r}\}
\]
\[
\{(\text{vars} x ; s) \ M_{r}\} \rightarrow \{(s) \rightarrow \{x \rightarrow 0\} \ M_{r}\}
\]

// State initialization:
\[
\{(X, X_{I} \rightarrow I) \ M_{r}\} \rightarrow \{(X \rightarrow I \rightarrow X_{I} \rightarrow I) \ M_{r}\}
\]

Figure 3.45: \(\mathcal{R}_{\text{CHAM(IMP)}}\): The CHAM of IMP in rewriting logic.
corresponding to all the syntax that we need in order to define the IMP semantics, which includes syntax for language constructs, for evaluation contexts, and for the state and state initialization.

The rewrite rules in Figure 3.45 are straightforward, following the transformation described in Figure 3.44. We grouped them in four categories: (1) the airlock rule is reversible and precisely captures the Airlock Law of the CHAM; (2) the heating/cooling rules, also reversible, capture the evaluation strategies of IMP’s language constructs (see Figure 3.41); (3) the semantic rules are irreversible and capture the computational steps of the IMP semantics (see Figure 3.42); (4) the state initialization rule corresponds to the heating rule in Figure 3.42.

Our CHAM-based rewriting logic semantics of IMP in Figure 3.45 follows blindly the CHAM of IMP in Figures 3.41 and 3.42. All it does is to mechanically apply the transformation in Figure 3.44, without making any attempts to optimize the resulting rewriting logic theory. For example, it is easy to see that the syntactic molecules will always contain only one molecule. Also, it is easy to see that the state molecule can be initialized in such a way that at any moment during the initialization rewriting sequence any subsolution containing a molecule of the form $x! \rightarrow i$, with $x!$ a proper list, will contain no other molecule. Finally, one can also notice that the top level solution will always contain only two molecules, namely what we called a syntactic solution and a state solution. All these observations suggest that we can optimize the rewriting logic theory in Figure 3.45 by deleting the variable $Ms$ from every rule except the airlock ones. While one can do that for our simple IMP language here, one has to be careful with such “optimizations” in general. For example, we later on add threads to IMP (see Section 3.8), which implies that the top level solution will contain a dynamic number of syntactic subsolutions, one per thread; if we remove the $Ms$ variable from the lookup and assignment rules in Figure 3.45 then those rules will not work whenever there are more than two threads running concurrently. On the other hand, the $Ms$ variable in the rule for variable declarations can still be eliminated. The point is that one needs to exercise care when one attempts to hand-optimize the rewrite logic theories resulting from mechanical semantic translations.

The CHAM of IMP in Maude

Like for the previous semantics, it is relatively straightforward to mechanically translate the corresponding rewrite theories into Maude modules. However, unlike in the previous semantics, the resulting Maude modules are not immediately executable. The main problem is that, in spite of its elegant chemical metaphor, the CHAM was not conceived to be blindly executable. For example, most of the heating and cooling rules tend to be reversible, leading to non-termination of the underlying rewrite relation. Non-termination is not a problem per se in rewriting logic and in Maude, because one can still use other formal analysis capabilities of these such as search and model checking, but from a purely pragmatic perspective it is rather inconvenient not to be able to execute an operational semantics of a language, particularly of a simple one like our IMP. Moreover, since the state space of a CHAM can very quickly grow to unmanageable sizes even when the state space of the represented program is quite small, a direct representation of a CHAM in Maude can easily end up having only a theoretical relevance.

Before addressing the non-termination issue, it is instructive to discuss how a tool like Maude can help us pinpoint and highlight potential problems in our definitions. For example, we have previously seen how we failed, in two different ways, to use CHAM’s airlock operator to define the evaluation strategies of the various IMP language constructs. We have noticed those problems with using the airlock for evaluation strategies by actually experimenting with CHAM definitions in Maude, more precisely by using Maude’s search command to explore different behaviors of a
mod CHAM is
  sorts Molecule Solution Bag{Molecule} .

  --- ... and so on
endm

Figure 3.46: Failed attempts to represent the CHAM of IMP in Maude using the airlock mechanism to define evaluation strategies. This figure also highlights the inconvenience of redefining IMP’s syntax (the module IMP-CHAM-SYNTAX needs to redefine the IMP syntax as molecule constructs).
program. We next discuss how one can use Maude to find out that both our attempts to use airlock for evaluation strategies fail. Figure 3.46 shows all the needed modules. CHAM defines the generic syntax of the chemical abstract machine together with its airlock rules in Maude, assuming only one type of molecule. IMP-CHAM-SYNTAX defines the syntax of IMP as well as the syntax of IMP’s evaluation contexts as a syntax for molecules; since there is only one syntactic category for syntax now, namely Molecule, adding □ as a Molecule constant allows for Molecule to also include all the IMP evaluation contexts, as well as many other “garbage” terms (e.g., □+□, etc.). The module IMP-HEATING-COOLING-CHAM-FAILED-1 represents in Maude, using the general translation of CHAM rules into rewriting logic rules shown in Figure 3.44, heating/cooling rules of the form

\[ a_1 + a_2 \Rightarrow a_1 < (\square + a_2) \]

Only two such groups of rules are shown, which is enough to show that we have a problem. Indeed, all four Maude search commands below succeed:

\[
\begin{align*}
s & \text{search}[1] \{| 3 \div (1 + 2) |\} \Rightarrow^* \{| 1 (\square + 2) (3 \div \square) |\} . \\
s & \text{search}[1] \{| 1 (\square + 2) (3 \div \square) |\} \Rightarrow^* \{| 3 \div (1 + 2) |\} . \\
s & \text{search}[1] \{| (3 \div 1) + 2 |\} \Rightarrow^* \{| 1 (\square + 2) (3 \div \square) |\} . \\
s & \text{search}[1] \{| 1 (\square + 2) (3 \div \square) |\} \Rightarrow^* \{| (3 \div 1) + 2 |\} .
\end{align*}
\]

That means that the Maude solution terms \{| 3 \div (1 + 2) |\} and \{| (3 \div 1) + 2 |\} can rewrite into each other, which is clearly wrong. Similarly, IMP-HEATING-COOLING-CHAM-FAILED-2 represents in Maude heating/cooling rules of the form

\[ (a_1 + a_2) \triangleleft c \Rightarrow a_1 \triangleleft (\square + a_2) \triangleleft c \]

One can now check that this second approach gives us what we wanted, that is, a chemical representation of syntax where each subsolution directly contains no more than one □:

\[
\begin{align*}
s & \text{search}[1] \{| 3 \div (1 + 2) |\} \Rightarrow^* \{| 1 \{| (\square + 2) \{| 3 \div \square |\} \{| \square |\} \} |\} . \\
s & \text{search}[1] \{| (3 \div 1) + 2 |\} \Rightarrow^* \{| 1 \{| (3 \div \square) \{| \square + 2 |\} \{| \square |\} \} |\} .
\end{align*}
\]

Indeed, both Maude search commands above succeed. Unfortunately, the following commands

\[
\begin{align*}
s & \text{search}[1] \{| 3 \div (1 + 2) |\} \Rightarrow^* \{| 1 \{\square + 2 \} \{| 3 \div \square \} \{| \square \} \} . \\
s & \text{search}[1] \{| 1 \{| \square + 2 \} \{| 3 \div \square \} \{| \square \} \} \Rightarrow^* \{| 3 \div (1 + 2) |\} . \\
s & \text{search}[1] \{| (3 \div 1) + 2 |\} \Rightarrow^* \{| 1 \{| \square + 2 \} \{| 3 \div \square \} \{| \square \} \} . \\
s & \text{search}[1] \{| 1 \{| \square + 2 \} \{| 3 \div \square \} \{| \square \} \} \Rightarrow^* \{| (3 \div 1) + 2 |\} .
\end{align*}
\]

also succeed, showing that our second attempt to use the airlock for evaluation strategies fails, too.

One could also try the following, which should also succeed (proof is the searches above):

\[
\begin{align*}
s & \text{search}[1] \{| 3 \div (1 + 2) |\} \Rightarrow^* \{| (3 \div 1) + 2 |\} . \\
s & \text{search}[1] \{| (3 \div 1) + 2 |\} \Rightarrow^* \{| 3 \div (1 + 2) |\} .
\end{align*}
\]

However, on our machine (Linux, 2.4GHz, 8GB memory) Maude 2 ran out of memory after several minutes when asked to execute any of the two search commands above.

Figures 3.47, 3.48 and 3.49 give a correct Maude representation of CHAM(IMP), based on the rewrite logic theory \( R_{\text{CHAM(IMP)}} \) in Figure 3.45. Three important observations were the guiding factors of our Maude semantics of CHAM(IMP):

177
While the approach to syntax in Figure 3.46 elegantly allows to include the syntax of evaluation contexts into the syntax of molecules by simply defining $\Box$ as a molecular construct, unfortunately it still requires us to redefine the entire syntax of IMP into specific constructs for molecules. This is inconvenient at best. We can do better by simply subsorting to $\text{Molecule}$ all those syntactic categories that the approach in Figure 3.46 would collapse into $\text{Molecule}$. This way, any fragment of IMP code parses to a subsort of $\text{Molecule}$, so in particular to $\text{Molecule}$. Unfortunately, evaluation contexts are now ill-formed; for example, $\Box + 2$ attempts to sum a molecule with an integer, which does not parse. To fix this, we define a new sort for the $\Box$ constant, say $\text{Hole}$, and declare it as a subsort of each IMP syntactic category that is subsorted to $\text{Molecule}$. In particular, $\text{Hole}$ is a subsort of $\text{AExp}$, so $\Box + 2$ parses to $\text{AExp}$.

As discussed above, most of CHAM’s heating/cooling rules are reversible and thus, when regarded as rewrite rules, lead to non-termination. To avoid non-termination, we restrict the heating/cooling rules so that heating only applies when the “heated” subterm has computational contents (i.e., it is not a result) while cooling only applies when the “cooled” term is completely processed (i.e., it is a result). This way, the heating and the cooling rules are applied in complementary situations, in particular they are not reversible anymore, thus avoiding non-termination. To achieve this, we introduce a subsort $\text{Result}$ of $\text{Molecule}$, together with subsorts of it corresponding to each syntactic category of IMP as well as with an explicit declaration of IMP’s results as appropriate terms of corresponding result sort.

The CHAM’s philosophy is to represent data, in particular program states, using its built-in support for solutions as multisets of molecules, and to use airlock operations to extract pieces of data from such solutions whenever needed. This philosophy is justified both by chemical and by mathematical intuitions, namely that one needs an additional step to “observe” inside a solution and, respectively, that multiset matching is a complex operation (it is actually an intractable problem) whose complexity cannot be simply “swept under the carpet”. While we agree with these justifications for the airlock operator, one should also note that impressive progress has been made in the last two decades, after the proposal of the chemical abstract machine, in terms of multiset matching. For example, languages like Maude build upon very

Figure 3.49: The CHAM of IMP in Maude.

well-engineered multiset matching techniques. We believe that these recent developments justify us, at least in practical language definitions, to replace the expensive airlock operation of the CHAM with the more available and efficient multiset matching of Maude.

Figure 3.47 shows the generic CHAM syntax that we extend in order to define CHAM(IM). Since we use Maude’s multiset matching instead of state airlock and since we cannot use the airlock for evaluation strategies either, there is effectively no need for the airlock in our Maude definition of CHAM(IM). Moreover, since the airlock rules are reversible, their introduction would yield non-termination. Consequently, we have plenty of reasons to eliminate them, which is reflected in our CHAM module in Figure 3.47. The Maude module in Figure 3.48 defines the evaluation strategies of IMP’s constructs and should now be clear: in addition to the syntactic details discussed above, it simply gives the Maude representation of the heating/cooling rules in Figure 3.45. Finally, the Maude module in Figure 3.49 implements the semantic rules and the state initialization heating rule in Figure 3.45, replacing the state airlock operation by multiset matching.

To test the heating/cooling rules, one can write Maude commands such as the two search commands below, asking Maude to search for all heatings of a given syntactic molecule (the sort of X, Id, is already declared in the last module):

search {| X := 3 / (X + 2) |} =>! Sol:Solution .

search {| X := (Y:Id + Z:Id) / (X + 2) |} =>! Sol:Solution .

The former gives only one solution, because heating can only take place on non-result subexpressions

Solution 1 (state 4)
states: 5 rewrites: 22 in ... cpu (... real) (... rewrites/second)
Sol:Solution --> |{ X ~> [] | 2 ~> 3 / [] ~> X := [] ~> [] } |

but the latter gives three solutions:

Solution 1 (state 5)
states: 8 rewrites: 31 in ... cpu (... real) (... rewrites/second)

180
Each of the solutions represents a completely heated term (we used =>! in the search commands) and corresponds to a particular order of evaluation of the subexpression in question. The three solutions of the second search command above reflect all possible orders of evaluation allowed by our Maude semantics of CHAM(IMP). Interestingly, note that there is no order in which \( X \) is looked up in between \( Y \) and \( Z \). This is not a problem for our simple IMP language in this section, but it may result in loss of behaviors when we extend our semantics to IMP++ in Section 3.8. Indeed, it may be that other threads modify the values of \( X, Y, \) and \( Z \) while the expression above is evaluated by another thread in such a way that behaviors are lost if \( X \) is not allowed to be looked up between \( Y \) and \( Z \). Consequently, our orientation of the heating/cooling rules came at a price: we lost the fully non-deterministic order of evaluation of the arguments of strict operators; what we obtained is a non-deterministic choice evaluation strategy (an order of evaluation is non-deterministically chosen and cannot be changed during the evaluation of the expression —this is discussed in more depth in Section 3.8).

Maude can now act as an execution engine for CHAM(IMP). For example, the Maude command

\[
\text{rewrite} \{ | \text{sumPgm} | \} .
\]

where \text{sumPgm} is the first program defined in the module \text{IMP-PROGRAMS} in Figure 3.4 produces a result of the form:

\[
\text{rewrites: 7343 in ... cpu (... real) (... rewrites/second)}
\]
\[
\text{result Solution: \{ | \{ \text{skip} \} \{ | n |-> 0 & s |-> 5050 | | \} | \}}
\]

Like in the previous Maude semantics, one can also search for all possible behaviors of a program using \text{search} commands such as

\[
\text{search} \{ | \text{sumPgm} | \} =>! \text{Sol:Solution} .
\]

Like before, only one behavior will be discovered (IMP is deterministic so far). However, an unexpectedly large number of states is generated, 3918 versus the 1509 states generated by the previous small-step semantics), mainly due to the multiple ways to apply the heating/cooling rules:

\[
\text{Solution 1 (state 3918)}
\]
\[
\text{states: 3919 rewrites: 12458 in ... cpu (... real) (... rewrites/second)}
\]
\[
\text{Sol:Solution --\{ | \{ \text{skip} \} \{ | n |-> 0 & s |-> 5050 | | \} | \}}
\]

Notes

The chemical abstract machine, abbreviated CHAM, was introduced by Berry and Boudol in 1990 \[10,11\]. In spite of its operational feel, the CHAM should not be mistakenly taken for a variant of (small-step) SOS. In fact, Berry and Boudol presented the CHAM as an alternative to SOS, to address a number of limitations inherent to SOS, particularly its lack of true concurrency and what
they called SOS’ “rigidity to syntax”. The basic metaphor giving its name to the CHAM was inspired
by Banâtre and Le Métayer’s GAMMA language [5, 6, 7], which was the first to view a distributed
state as a solution in which many molecules float, and the first to understand concurrent transitions
as reactions that can occur simultaneously in many points of the solution. GAMMA was proposed
as a highly-parallel programming language, together with a stepwise program derivation approach
that allows to develop provably correct GAMMA programs. However, following the stepwise
derivation approach to writing GAMMA programs is not as straightforward as writing CHAM rules.
Moreover, CHAM’s nesting of solutions allows for structurally more elaborate encodings of data
and in particular for more computational locality than GAMMA. Also, the CHAM appears to be
more suitable as a framework for defining semantics of programming languages than the GAMMA
language; the latter was mainly conceived as a programming language itself, suitable for executing
parallel programs on parallel machines [4], rather than as a semantic framework.

The distinction between heating, cooling and reaction rules in CHAM is in general left to the
user. There are no well-accepted criteria and/or principles stating when a rule should be in one
category or another. For example, should a rule that cleans up a solution by removing residue
molecules be a heating or a cooling rule? We prefer to think of it as a cooling rule, because it falls
under the broad category of rules which “structurally rearrange the solution after reactions take
place” which we methodologically decided to call cooling rules. However, the authors of the CHAM
prefer to consider such rules to be heating rules, with the intuition that “the residue molecules
evaporate when heated” [11]. While the distinction between heating and cooling rules may have a
flavor of subjectivity, the distinction between actual reaction rules and heating/cooling rules is more
important because it gives the computational granularity of one’s CHAM. Indeed, it is common
to abstract away the heating/cooling steps in a CHAM rewriting sequence as “internal steps” and
then define various relations of interest on the remaining reaction steps possibly relating different
CHAMS, such as behavioral equivalence, simulation and/or bisimulation relations [10, 11].

The technique we used in this section to reversibly and possibly non-deterministically sequentialize
the program syntax by heating/cooling it into a list of computational tasks was borrowed from the
K framework [68, 66, 48, 64] (see Section 5). This mechanism is also reminiscent of Danvy
and Nielsen’s refocusing technique [22, 23], used to execute reduction semantics with evaluation
contexts by decomposing evaluation contexts into stacks and then only incrementally modifying
these stacks during the reduction process. Our representation of the CHAM into rewriting logic was
inspired from related representations by Şerbănuţă et al. [72] and by Meseguer [42]. However, our
representation differs in that it enforces the CHAM rewriting to only take place in solutions, this way
being completely faithful to the intended meaning of the CHAM reactions, while the representations
in [72, 42] are slightly more permissive, allowing rewrites to take place everywhere rules match; as
explained, this is relevant only when the left-hand side of the rule contains precisely one molecule.

We conclude this section with a note on the concurrency of CHAM rewriting. As already
explained, we are not aware of any formal definition of a CHAM rewriting relation that captures the
true concurrent computation advocated by the CHAM. This is unfortunate, because its concurrency
potential is one of the most appealing aspects of the CHAM (in addition to its “coolness” factor).
Moreover, as already discussed (after Theorem 10), our rewriting logic representation of the CHAM
is faithful only with respect to one non-concurrent step and interleaves steps taking place within

\footnote{Meseguer [42] was published in the same volume of the Journal of Theoretical Computer Science as the CHAM extended paper [11] (the first CHAM paper [10] was published two years before, in 1990, same as the first papers on rewriting logic [40, 39, 41]).}
the same solutions no matter whether they involve common molecules or not, so we cannot borrow
rewriting logic’s concurrency to obtain a concurrent semantics for the CHAM. What can be done,
however, is to attempt a different representation of the CHAM into rewriting logic based on ideas
proposed by Meseguer in [43] to capture (a limited form of) graph rewriting by means of equational
encodings. The encoding in [43] is theoretically important, but, unfortunately, yields rewrite logic
theories which are not feasible in practice using the current implementation of Maude.
