3.3 Small-Step Structural Operational Semantics (Small-Step SOS)

Known also under the names transition semantics and reduction semantics, small-step structural operational semantics, or “small-step SOS” for short, formally captures the intuitive notion of one atomic computational step. Unlike in big-step SOS where one defines all computation steps in one transition, in a small-step SOS definition a transition encodes only one step of computation. To distinguish small-step from big-step transitions, we use a plain arrow “→” instead of “⇒”. To execute a small-step SOS definition, or to relate it to a big-step definition, we need to transitively close the small-step transition relation. Indeed, the conceptual relationship between big-step SOS and small-step SOS is that for any configuration \( C \) and any result configuration \( R \), \( C \not\leadsto R \) if and only if \( C \rightarrow^* R \). Small-step semantics is typically preferred over big-step semantics when defining languages with a high-degree of non-determinism, such as, for example, concurrent languages, because in a small-step semantics one has a direct control over what can execute and when.

Under small-step semantics, the sequents are also relations of configurations like in big-step SOS, but in small-step SOS they are written \( C \rightarrow C' \) and have the meaning that \( C' \) is a configuration obtained from \( C \) after one step of computation. A small-step SOS rule therefore has the form

\[
C_1 \rightarrow C'_1, \ C_2 \rightarrow C'_2, \ldots, \ C_n \rightarrow C'_n \\
\overset{\rightarrow}{\rightarrow} \quad C \rightarrow C'
\]

where \( C, C', C_1, C_2, C_2', \ldots, C_n, C'_n \) are configurations holding fragments of program together with all the needed semantic components, like in big-step SOS. Unlike in big-step SOS, the result configurations do not need to be explicitly defined because in small-step they are implicit: they are precisely those configurations which cannot be reduced anymore using the one-step relation.

Given a configuration holding a fragment of program, a small-step of computation typically takes place in some sub-part of the fragment of program. However, when each of the sub-parts is already reduced, then the small-step can apply on the part itself. A small-step SOS is therefore finer-grain than big-step SOS, and thus more verbose, because one has to cover all the cases where a computation step can take place. For example, the small-step SOS of addition in IMP is

\[
\begin{align*}
\langle a_1, \sigma \rangle \rightarrow \langle a'_1, \sigma \rangle \\
\langle a_1 + a_2, \sigma \rangle \rightarrow \langle a'_1 + a_2, \sigma \rangle \\
\langle a_2, \sigma \rangle \rightarrow \langle a'_2, \sigma \rangle \\
\langle a_1 + a_2, \sigma \rangle \rightarrow \langle a'_1 + a'_2, \sigma \rangle \\
\langle i_1 + i_2, \sigma \rangle \rightarrow \langle i_1 + i_2, \sigma \rangle
\end{align*}
\]

Here, the meaning of a relation \( \langle a, \sigma \rangle \rightarrow \langle a', \sigma \rangle \) is that arithmetic expression \( a \) in state \( \sigma \) is reduced, in one small-step, to arithmetic expression \( a' \) and the state stays unchanged.

The rules above rely on the fact that expression evaluation in IMP has no side effects. If there were side effects, like in the IMP extension in Section 3.9, then the \( \sigma \)'s in the right-hand-side configurations above would need to change to a different symbol, say \( \sigma' \), to account for the possibility that the small-step in the condition of the rules, and implicitly in their conclusion, may change the state as well. While in big-step SOS it is more common to derive sequents of the form \( \langle a, \sigma \rangle \not\leadsto \langle i \rangle \) than of the form \( \langle a, \sigma \rangle \leadsto \langle i, \sigma \rangle \), in small-step SOS the opposite tends to be norm, that is, it is more common to derive sequents of the form \( \langle a, \sigma \rangle \rightarrow \langle a', \sigma \rangle \) than of the form \( \langle a, \sigma \rangle \rightarrow \langle a' \rangle \). Nevertheless, the latter sequent type also works when defining languages like IMP whose expressions are side-effect
sorts:
  Configuration

operations:
  \( \langle \_ , \_ \rangle : AExp \times State \rightarrow Configuration \)
  \( \langle \_ , \_ \rangle : BExp \times State \rightarrow Configuration \)
  \( \langle \_ , \_ \rangle : Stmt \times State \rightarrow Configuration \)
  \( \_ \_ : Pgm \rightarrow Configuration \)

Figure 3.10: IMP small-step SOS configurations as an algebraic signature.

free (see Exercise 40). Some language designers may prefer this latter style, to keep sequents minimal. However, even if one prefers these simpler sequents, for the same reason of a uniform notation like in big-step SOS, we prefer to keep the angle brackets in the right hand sides of the transition relations; in other words, we write \( \langle a, \sigma \rangle \rightarrow \langle a' \rangle \) and not \( \langle a, \sigma \rangle \rightarrow a' \).

3.3.1 IMP Configurations for Small-Step SOS

The configurations needed for the small-step semantics of IMP are a subset of those needed for its big-step semantics discussed in Section 3.2.1. Indeed, we still need all the two-component configurations containing a fragment of program and a state, but, for the particular small-step SOS style that we follow in this section, we do not need those result configurations of big-step SOS containing only a value or only a state. If one prefers to instead follow the “minimalist” style as in Exercise 40, then one would also need the other configuration types. We enumerate all the configuration types needed for the small-step SOS of IMP as given in the reminder of this section:

- \( \langle a, \sigma \rangle \) grouping arithmetic expressions \( a \) and states \( \sigma \);
- \( \langle b, \sigma \rangle \) grouping boolean expressions \( b \) and states \( \sigma \);
- \( \langle s, \sigma \rangle \) grouping statements \( s \) and states \( \sigma \);
- \( \langle p \rangle \) holding programs \( p \);

We still need the one-component configuration holding only a program, because we still want to reduce a program in the default initial state (empty) without having to mention the empty state.

IMP Small-Step SOS Configurations as an Algebraic Signature

Figure 3.10 shows an algebraic signature defining the IMP configurations above which needed for the subsequent small-step operational semantics. We defined this algebraic signature in the same style and following the same assumptions as those for big-step SOS in Section 3.2.1.

3.3.2 The Small-Step SOS Rules of IMP

Figures 3.11 and 3.12 show all the rules in our IMP small-step SOS proof system, the former showing the rules corresponding to expressions, both arithmetic and boolean, and the latter showing those rules corresponding to statements. The sequents that this proof system derives have the forms
(x, σ) → ⟨σ(x), σ⟩  (SMALLSTEP-Lookup)

⟨a₁, σ⟩ → ⟨a'₁, σ⟩  (SMALLSTEP-Add-Arg1)

⟨a₁ + a₂, σ⟩ → ⟨a'₁ + a₂, σ⟩  (SMALLSTEP-Add)

⟨a₂, σ⟩ → ⟨a'₂, σ⟩  (SMALLSTEP-Add-Arg2)

⟨a₁ + a₂, σ⟩ → ⟨a₁ + a₂', σ⟩

⟨a₁, σ⟩ → ⟨a'₁, σ⟩

i₁ + i₂, σ → ⟨i₁ + int i₂, σ⟩

⟨a₁, σ⟩ → ⟨a'₁, σ⟩  (SMALLSTEP-Add-Arg1)

⟨a₂, σ⟩ → ⟨a'₂, σ⟩  (SMALLSTEP-Add-Arg2)

⟨a₁ / a₂, σ⟩ → ⟨a₁ / a₂, σ⟩

⟨i₁ / i₂, σ⟩ → ⟨i₁ / int i₂, σ⟩  when i₂ ≠ 0  (SMALLSTEP-Div)

⟨a₁, σ⟩ → ⟨a'₁, σ⟩

⟨a₁ ≤ a₂, σ⟩ → ⟨a₁' ≤ a₂, σ⟩  (SMALLSTEP-Leq-Arg1)

⟨a₂, σ⟩ → ⟨a₂', σ⟩  (SMALLSTEP-Leq-Arg2)

⟨i₁ ≤ i₂, σ⟩ → ⟨i₁ ≤ int i₂, σ⟩  (SMALLSTEP-Leq)

⟨b, σ⟩ → ⟨b', σ⟩  (SMALLSTEP-Not-Arg)

⟨not b, σ⟩ → ⟨not b', σ⟩

⟨not true, σ⟩ → ⟨false, σ⟩  (SMALLSTEP-Not-True)

⟨not false, σ⟩ → ⟨true, σ⟩  (SMALLSTEP-Not-False)

⟨b₁, σ⟩ → ⟨b₁', σ⟩  (SMALLSTEP-And-Arg1)

⟨b₁ and b₂, σ⟩ → ⟨b₁' and b₂, σ⟩  (SMALLSTEP-And)

⟨false and b₂, σ⟩ → ⟨false, σ⟩  (SMALLSTEP-And-False)

⟨true and b₂, σ⟩ → ⟨b₂, σ⟩  (SMALLSTEP-And-True)

Figure 3.11: SMALLSTEP(IMP) — Small-step SOS of IMP expressions (i₁, i₂ ∈ Int; x ∈ VarId; a₁, a₁', a₂, a₂', b, b', b₁, b₁', b₂ ∈ BExp; σ ∈ State).

89
\( \langle a, \sigma \rangle \rightarrow \langle a', \sigma \rangle, \langle b, \sigma \rangle \rightarrow \langle b', \sigma \rangle, \langle s, \sigma \rangle \rightarrow \langle s', \sigma' \rangle, \) and \( \langle p \rangle \rightarrow \langle s, \sigma \rangle, \) where \( a \) ranges over \( AExp, \) \( b \) over \( BExp, \) \( s \) over \( Stmt, \) \( p \) over \( Pgm, \) and \( \sigma \) and \( \sigma' \) over \( State. \)

The meaning of derived triples of the form \( \langle a, \sigma \rangle \rightarrow \langle a', \sigma \rangle \) is that given state \( \sigma \), the arithmetic expression \( a \) reduces in one (small) step to the arithmetic expression \( a' \) and the state \( \sigma \) stays unchanged. The meaning of \( \langle b, \sigma \rangle \rightarrow \langle b', \sigma \rangle \) is similar but with boolean expressions instead of arithmetic expressions. The meaning of \( \langle s, \sigma \rangle \rightarrow \langle s', \sigma' \rangle \) is that statement \( s \) in state \( \sigma \) reduces in one step to statement \( s' \) in a potentially modified state \( \sigma' \). The meaning of \( \langle p \rangle \rightarrow \langle s, \sigma \rangle \) is that program \( p \) reduces in one step to statement \( s \) in state \( \sigma \) (as expected, whenever such sequents can be derived, the statement \( s \) is the body of \( p \) and the state \( \sigma \) initializes to 0 the variables declared by \( p \)). The reason for which the state stays unchanged in the sequents corresponding to arithmetic and boolean expressions is because, as discussed, IMP’s expressions currently have no side effects; we will have to change these rules later on in Section 3.8 when we add a variable increment arithmetic expression construct to IMP. A small-step reduction of a statement may or may not change the state, so we use a different symbol in the right-hand side of statement transitions, \( \sigma' \), to cover both cases.

We next discuss each of the small-step SOS rules of IMP in Figures 3.11 and 3.12 Before we start, note that we have no small-step rules for reducing constant (integer or boolean) expressions to their corresponding values as we had in big-step SOS (i.e., no rules corresponding to \( \text{(BigStep-Int)} \) and \( \text{(BigStep-Bool)} \) in Figure 3.7). Indeed, we do not want to have small-step SOS rules of the form \( \langle v, \sigma \rangle \rightarrow \langle v, \sigma \rangle \) because no one-step reductions are further desired on values \( v \): adding such rules would lead to undesired divergent SOS reductions later on when we consider the transitive closure of the one-step relation \( \rightarrow \). Recall that the big-step SOS relation \( \downarrow \) captured all the reduction steps at once, including zero steps, and thus it did not need to be transitively closed like the small-step relation \( \rightarrow \), so evaluating values to themselves was not problematic in big-step SOS.

The rule \( \text{(SmallStep-Lookup)} \) happens to be almost the same as in the big-step SOS; that’s because variable lookup is an atomic-step operation both in big-step and in small-step SOS. The rules \( \text{(SmallStep-Add-Arg1)}, \text{(SmallStep-Add-Arg2)}, \) and \( \text{(SmallStep-Add)} \) give the small-step semantics of addition, and \( \text{(SmallStep-Div-Arg1)}, \text{(SmallStep-Div-Arg2)}, \) and \( \text{(SmallStep-Div)} \) give the small-step semantics of division, each covering all the three cases where a small-step reduction can take place. The first two cases in each group may apply non-deterministically. Recall from Section 3.2 that big-step SOS was inappropriate for defining the desired non-deterministic evaluation strategies for \( + \) and \( / \). Fortunately, that was not a big problem for IMP, because its intended non-deterministic constructs are side-effect free. Therefore, the intended non-deterministic evaluation strategies of these particular language constructs did not affect the overall determinism of the IMP language, thus making its deterministic (see Exercise 13) big-step SOS definition in Section 3.2 acceptable. As expected, the non-deterministic evaluation strategies of \( + \) and \( / \), which this time can be appropriately captured within the small-step SOS, will not affect the overall determinism of the IMP language (that is, the reflective/transitive closure \( \rightarrow^* \) of \( \rightarrow \); see Theorem 3).

**Exercise 37.** Change the small-step rules for \( / \) so that it short-circuits when \( a_1 \) evaluates to 0.

The rules \( \text{(SmallStep-Leq-Arg1)}, \text{(SmallStep-Leq-Arg2)}, \) and \( \text{(SmallStep-Leq)} \) give the deterministic, sequential small-step SOS of \( \leq \). The first rule applies whenever \( a_1 \) is not an integer, then the second rule applies when \( a_1 \) is an integer but \( a_2 \) is not an integer, and finally, when both \( a_1 \) and \( a_2 \) are integers, the third rule applies. The rules \( \text{(SmallStep-Not-Arg)}, \text{(SmallStep-Not-True)} \) and \( \text{(SmallStep-Not-False)} \) are self-explanatory, and the rules \( \text{(SmallStep-And-Arg1)}, \text{(SmallStep-And-False)} \) and \( \text{(SmallStep-And-True)} \) give the short-circuited semantics of \( \text{and} \); indeed, note that \( b_2 \) will never be reduced if \( b_1 \) is not first reduced to \text{true}.

\langle \text{while } b \text{ do } s, \sigma \rangle & \rightarrow \langle \text{if } b \text{ then } (s ; \text{while } b \text{ do } s) \text{ else } \text{skip}, \sigma \rangle & & \text{(SmallStep-While)} \\
\langle \text{vars } x; l ; s \rangle & \rightarrow \langle s, (x \mapsto 0) \rangle & & \text{(SmallStep-Vars)}
\end{align*}
\]

Figure 3.12: SmallStep(IMP) — Small-step SOS of IMP statements \((i \in \text{Int}; x \in \text{VarId}; x; l \in \text{List} \{\text{VarId}\}; a, a' \in \text{AExp}; b, b' \in \text{BExp}; s, s_1, s_1', s_2, s_2' \in \text{Stmt}; \sigma, \sigma' \in \text{State})\).

**Exercise 38.** Change the small-step SOS of the IMP conjunction so that it is not short-circuited.

Before we continue with the remaining small-step SOS rules for statements, let us see an example of a small-step SOS reduction using the rules discussed so far; as in the case of the big-step SOS rules in Section 3.2 recall that the small-step SOS rules are also rule schemas, that is, they are parametric in the (meta-)variables \(a, a_1, b, s, \sigma, \text{etc.}\) The following is a correct derivation, where \(x\) and \(y\) are any variables and \(\sigma\) is any state with \(\sigma[x] = 1\):

\[
\begin{align*}
\langle x, \sigma \rangle & \rightarrow \langle 1, \sigma \rangle \\
\langle y/x, \sigma \rangle & \rightarrow \langle y/1, \sigma \rangle \\
\langle x + (y/x), \sigma \rangle & \rightarrow \langle x + (y/1), \sigma \rangle \\
\langle (x + (y/x)) \text{ <= } x, \sigma \rangle & \rightarrow \langle (x + (y/1)) \text{ <= } x, \sigma \rangle
\end{align*}
\]

The above can be regarded as a proof of the fact that replacing the second occurrence of \(x\) by 1 is a correct one-step computation of IMP, as defined using the small-step SOS rules discussed so far.

Let us now discuss the small-step SOS rules of statements in Figure 3.12. Unlike the reduction of expressions, a reduction step of a statement may also change the state. Rule (SmallStep-Asgn-Arg2) reduces the second argument (which is an arithmetic expression) of an assignment statement whenever possible. When the second argument is already fully reduced (i.e., it is an integer value), the rule (SmallStep-Asgn) reduces the assignment statement to \(\text{skip}\), at the same time updating the state accordingly. One could argue that this reduction of assignment to \(\text{skip}\) is an artificial...
\[ C \rightarrow^* C \quad (\text{SmallStep-Closure-Stop}) \]

\[
\frac{C \rightarrow C'', \ C'' \rightarrow^* C'}{C \rightarrow^* C'} \quad (\text{SmallStep-Closure-More})
\]

Figure 3.13: SmallStep(IMP) — Reflexive/transitive closure of the small-step SOS relation, which is the same for any small-step SOS of any language or calculus (\( C, C', C'' \in \text{Configuration} \)).

and undesired step, which thus affects the intended computational granularity of the language; the sophisticated language designer who does not want to introduce any artificial steps as an artifact of the underlying definitional style can use instead the small-step SOS style in Exercise 40 and this way eliminate this additional small-step (note, however, that the style in Exercise 40 will require more rules and more types of configurations, so from that point of view is more complex).

The rules \((\text{SmallStep-Seq-Arg1})\) and \((\text{SmallStep-Seq-Skip})\) give the small-step SOS of sequential composition: if the first statement is reducible then reduce it, otherwise, if it is \texttt{skip}, move on in a small-step to the second statement. The three rules for the conditional, namely \((\text{SmallStep-If-Arg1})\), \((\text{SmallStep-If-True})\) and \((\text{SmallStep-If-False})\) are straightforward; note that the two branches are never reduced when the condition can still be reduced. The small-step SOS of \texttt{while} simply unrolls the loop once; this unrolling semantics seems as natural as it can be, but one should notice that it actually generates an artificial computational step.

Exercise 39. Give an alternative small-step SOS definition of \texttt{while} which wastes no computational step. \texttt{Hint:} do a case analysis on \( b \), like in the rules of the conditional.

Finally, \((\text{SmallStep-Vars})\) gives the semantics of programs by reducing them to their body statement in the expected state formed by initializing all the declared variables to 0.

Exercise 40. Modify the small-step SOS definition of \texttt{IMP} discussed above such that the configurations in the right-hand sides of the transition sequents are minimal (they should contain both a fragment of program and a state only when absolutely needed). What are the drawbacks of this minimalistic approach, compared to the small-step SOS semantics that we chose to follow above?

It is worthwhile noting that one has some flexibility in how to give a small-step SOS semantics to a language. The same holds true for almost any language definitional style, not only for SOS.

Exercise 41. Show that the small-step SOS resulting from Exercise 40 is equivalent to the one discussed above on arithmetic and boolean expressions, that is, \( \langle a, \sigma \rangle \rightarrow \langle a', \sigma \rangle \) derivable with the proof system above if and only if \( \langle a, \sigma \rangle \rightarrow \langle a' \rangle \) derivable with the proof system in Exercise 40, and similarly for boolean expressions. Also, show that the equivalence does not hold true for statements.

On Proof Derivations, Evaluation and Termination

To formally capture the notion of “sequence of transitions”, in Figure 3.13 we define the relation of reflexive/transitive closure of the small-step SOS transition.

Definition 17. Given appropriate \texttt{IMP} small-step SOS configurations \( C \) and \( C' \), the \texttt{IMP} small-step SOS sequent \( C \rightarrow C' \) is derivable, written SmallStep(IMP) \( \vdash C \rightarrow C' \), iff there is some proof tree rooted in \( C \rightarrow C' \) which is derivable using the proof system SmallStep(IMP) in Figures
In this case, we also say that \( C \) reduces in one step to \( C' \). Similarly, many-step sequent \( C \rightarrow^* C' \) is derivable, written \( \text{SmallStep}(\text{IMP}) \vdash C \rightarrow^* C' \), iff there is some proof tree rooted in \( C \rightarrow^* C' \) which is derivable using the proof system in Figures 3.11, 3.12, and 3.13. In this case, we also say that \( C \) reduces (in zero, one or more steps) to \( C' \). Configuration \( R \) is irreducible iff there is no configuration \( C \) such that \( \text{SmallStep}(\text{IMP}) \vdash R \rightarrow C \), and is result iff it has one of the forms \( \langle i, \sigma \rangle \), \( \langle t, \sigma \rangle \), or \( \langle \text{skip}, \sigma \rangle \), where \( i \in \text{Int} \), \( t \in \text{Bool} \), and \( \sigma \in \text{State} \). Finally, configuration \( C \) terminates under \( \text{SmallStep}(\text{IMP}) \) iff there is no infinite sequence of configuration \( C_0, C_1, \ldots \) such that \( C_0 = C \) and \( C_i \) reduces in one step to \( C_{i+1} \) for any natural number \( i \).

Result configurations are irreducible, but there are irreducible configurations which are not necessarily result configurations. For example, a configuration of the form \( \langle i/0, \sigma \rangle \) is irreducible but it is not a result. Like for big-step SOS, to “catch” division-by-zero within the semantics we need to add special “error” values/states and propagate them through all the language constructs.

**Exercise 42.** Add error values and state and modify the small-step semantics in Figures 3.11 and 3.12 to allow derivations of sequents whose right-hand side configurations contain error as their syntactic component. Also, experiment with more meaningful error messages.

Note that there are non-terminating sequences which repeat configurations, as well as non-terminating sequences in which all the configurations are distinct; an example of the former could be a sequence generated by reducing the statement “while true do skip”, while an example of the latter could be a sequence generated by reducing “while (n > 0) do n := n + 1”. Nevertheless, in the case of the simple IMP language, a configuration does not terminate if and only if it cannot reduce to an irreducible configuration:

**Exercise 43.** With the \( \text{SmallStep}(\text{IMP}) \) in Figures 3.11, 3.12, and 3.13 configuration \( C \) terminates iff there is some irreducible configuration \( R \) such that \( \text{SmallStep}(\text{IMP}) \vdash C \rightarrow^* R \).

This is not necessarily the case for non-deterministic languages, such as the IMP extension in Section 3.8, because reductions of configurations in such language semantics may non-deterministically choose steps that lead to termination, as well as steps that may not lead to termination. In the case of IMP though, the local non-determinism given by rules like (\( \text{SmallStep-Add-Arg1} \)) and (\( \text{SmallStep-Add-Arg2} \)) does not affect the overall determinism of the IMP language which, using the small-step SOS formalism above can be framed as follows:

**Exercise 44.** The small-step SOS definition of IMP is globally deterministic: if \( \text{SmallStep}(\text{IMP}) \vdash C \rightarrow^* R \) and \( \text{SmallStep}(\text{IMP}) \vdash C \rightarrow^* R' \) for irreducible configurations \( R \) and \( R' \), then \( R = R' \). Show the same result for the proof system detecting division-by-zero as in Exercise 42.

**Exercise 45.** Show that if \( \text{SmallStep}(\text{IMP}) \vdash C \rightarrow^* \langle i, \sigma \rangle \) for some configuration \( C \), integer \( i \) and state \( \sigma \), then \( C \) must be of the form \( \langle a, \sigma \rangle \) for some arithmetic expression \( a \). Show a similar result for boolean expressions. For statements, show that if \( \text{SmallStep}(\text{IMP}) \vdash C \rightarrow^* \langle \text{skip}, \sigma \rangle \) then \( C \) must be either of the form \( \langle s, \sigma' \rangle \) for some statement \( s \) and some state \( \sigma' \), or of the form \( \langle p \rangle \) for some program \( p \).

**Relating Big-Step and Small-Step SOS**

As expected, the reflexive/transitive closure \( \rightarrow^* \) of the small-step SOS relation captures the same “complete evaluation” meaning as the \( \Downarrow \) relation in big-step SOS (Section 3.2). Since for demonstrations reasons we deliberately worked with different result configurations in big-step and in small-step.
Theorem 3. The following equivalences hold for any $R$ addition to the one similarly obtained from the big-step SOS of that is step-for-step equivalent to the original small-step SOS of IMP formal system.

- $\text{SmallStep}(\text{IMP}) \vdash a, \sigma \rightarrow^* (i, \sigma')$ for some state $\sigma'$ iff $\text{BigStep}(\text{IMP}) \vdash a, \sigma \downarrow \{i\}$;
- $\text{SmallStep}(\text{IMP})' \vdash b, \sigma \rightarrow^* (t, \sigma')$ for some state $\sigma'$ iff $\text{BigStep}(\text{IMP}) \vdash b, \sigma \downarrow \{t\}$;
- $\text{SmallStep}(\text{IMP}) \vdash s, \sigma \rightarrow (\text{skip}, \sigma')$ for some state $\sigma'$ iff $\text{BigStep}(\text{IMP}) \vdash s, \sigma \downarrow \{\text{skip}\}$;
- $\text{SmallStep}(\text{IMP}) \vdash p \rightarrow^* (\text{skip}, \sigma)$ for some state $\sigma$ iff $\text{BigStep}(\text{IMP}) \vdash p \downarrow \{\sigma\}$.

Exercise 46. Prove Theorem 3.

Exercise 47. State and show a result similar to Theorem 3 but for the small-step and big-step SOS proof systems in Exercises 42 and 34 respectively.

Note that the small-step SOS relation is a recursive, or decidable problem: indeed, given configurations $C$ and $C'$, one can use the small-step proof system in Figures 3.11 and 3.12 to exhaustively check whether indeed $C \rightarrow C'$ is derivable or not. Moreover, since the rules for the reflexive/transitive closure relation $\rightarrow^*$ in Figure 3.13 can be used to systematically generate any sequence of reductions, we conclude that the relation $\rightarrow^*$ is recursively enumerable. Theorem 3 together with the discussion at the end of Section 3.2.2 in particular Exercise 36 tells us that $\rightarrow^*$ is properly recursively enumerable, that is, it cannot be recursive. This tells us, in particular, that non-termination of a program $p$ is equivalent to saying that $\text{SmallStep}(\text{IMP}) \vdash p \rightarrow^* \{\text{skip}, \sigma\}$ does not hold for any state $\sigma$. However, unlike in the case of big-step SOS where nothing else can be said about non-terminating programs, in the case of small-step SOS definitions one can use the small-step relation, $\rightarrow$, to observe “program executions” for any number of steps.

3.3.3 Small-Step SOS in Rewriting Logic

Like for big-step SOS, we can also associate a conditional rewrite rule to each small-step SOS rule and hereby obtain a rewrite logic theory that faithfully (i.e., step-for-step) captures the small-step SOS definition. An important technical aspect needs to be resolved, though. The rewriting relation of rewriting logic is by its nature reflexively and transitively closed. On the other hand the small-step SOS relation is not reflexively and transitively closed by default (its reflexive/transitive closure is typically defined ex post). Therefore, we need to devise mechanisms to “inhibit” rewriting logic’s reflexive, transitive and “uncontrolled” application of rules.

We first show that any small-step SOS, say $\text{SmallStep}$, can be mechanically translated into a rewriting logic theory, say $\mathcal{R}_{\text{SmallStep}}$, in such a way that the corresponding derivation relations are step-for-step equivalent, that is, $\text{SmallStep} \vdash C \rightarrow C'$ if and only if $\mathcal{R}_{\text{SmallStep}} \vdash C \rightarrow C'$, where $\mathcal{R}_{C \rightarrow C'}$ is the corresponding syntactic translation of the small-step SOS sequent $C \rightarrow C'$ into a rewrite logic sequent. Second, we apply our generic translation technique on the small-step SOS formal system $\text{SmallStep}(\text{IMP})$ defined in Section 3.3.2 and obtain a rewrite logic semantics of IMP that is step-for-step equivalent to the original small-step SOS of IMP. Finally, we show how $\mathcal{R}_{\text{SmallStep}(\text{IMP})}$ can be seamlessly defined in Maude, thus yielding another interpreter for IMP (in addition to the one similarly obtained from the big-step SOS of IMP in Section 3.2.3).
Faithful Embedding of Small-Step SOS into Rewriting Logic

Like for big-step SOS (Section 3.2.3), to define our translation from small-step SOS to rewriting logic generically, we assume that each parametric configuration $C$ admits an equivalent algebraic variant $\overline{C}$ as a term of sort $\text{Configuration}$ over an appropriate signature of configurations like the one that we defined for IMP in Section 3.2.1 (see Figure 3.6); moreover, each parameter in $C$ (e.g., arithmetic expression $a \in A\text{Exp}$) gets replaced by a variable of corresponding sort in $\overline{C}$ (e.g., variable $A$ of sort $A\text{Exp}$). Consider now a general-purpose small-step SOS rule of the form

$$C_1 \rightarrow C'_1, \ C_2 \rightarrow C'_2, \ldots, \ C_n \rightarrow C'_n \quad \text{where} \ C, C', C_1, C'_1, C_2, C'_2, \ldots, C_n, C'_n \ \text{are configurations holding fragments of program together with all the needed semantic components. Before we introduce our transformation, let us first discuss why the same straightforward transformation that we used in the case of big-step SOS,}$$

$$\overline{C} \rightarrow \overline{C'} \ \text{if} \ \overline{C_1} \rightarrow \overline{C'_1} \land \overline{C_2} \rightarrow \overline{C'_2} \land \ldots \land \overline{C_n} \rightarrow \overline{C'_n},$$

$$\langle X := A, \sigma \rangle \rightarrow \langle X := A', \sigma \rangle \ \text{if} \ \langle A, \sigma \rangle \rightarrow \langle A', \sigma \rangle$$

$$\langle X := I, \sigma \rangle \rightarrow \langle \text{skip}, \sigma[I/X] \rangle$$

The problem with these rules is that the rewrite of a configuration of the form $\langle x := i, \sigma \rangle$ for some $x \in \text{VarId}$, $i \in \text{Int}$ and $\sigma \in \text{State}$ may not terminate, applying forever the first rule: in rewriting logic, $\langle i, \sigma \rangle \rightarrow \langle i, \sigma \rangle$ because $\rightarrow$ is closed under reflexivity. Even if we may somehow solve this reflexivity aspect by defining and then including an additional condition $A \neq A'$, such rules still fail to capture the intended small-step transition, because $\rightarrow$ is also closed transitively in rewriting logic, so there could be many small-steps taking place in the condition of the first rule before the rule is applied.

To capture exactly one step of reduction, thus avoiding the inherent automatic reflexivity and transitive closure of the rewrite relation which is desirable in rewriting logic but not in reduction semantics, we can mark the left-hand-side (or alternatively the right-hand-side) configuration in each rewrite sequent to always be distinct from the other one; then each rewrite sequent comprises precisely one step, from a marked to an unmarked configuration (or alternatively the viceversa). For example, let us place a “$\circ$” in front of all the left-hand-side configurations and keep the right-hand-side configurations unchanged. Then the generic small-step SOS rule above translates into the following rewrite logic rule:

$$\circ\overline{C} \rightarrow \overline{C'} \ \text{if} \ \circ\overline{C_1} \rightarrow \overline{C'_1} \land \circ\overline{C_2} \rightarrow \overline{C'_2} \land \ldots \land \circ\overline{C_n} \rightarrow \overline{C'_n}.$$

One can metaphorically think of a marked configuration $\circ\overline{C}$ as a “hot” configuration that needs to be “cooled down” in one step, while of an unmarked configuration $\overline{C}$ as a “cool” one. Theorem 4 below shows as expected that a small-step SOS sequent $C \rightarrow C'$ is derivable if and only if the term $\circ\overline{C}$ rewrites in the corresponding rewrite theory to $\overline{C'}$ (which is a normal form). Thus, to enable the resulting rewrite system on a given configuration, one needs to first mark the configuration to be reduced (by placing a “$\circ$” in front of it) and then to let it rewrite to its normal form. Since the one-step reduction always terminates, the corresponding rewrite task also terminates.
sorts:
  ExtendedConfiguration
subsorts:
  Configuration < ExtendedConfiguration
operations:
  ○ : Configuration → ExtendedConfiguration     // reduce one step
  * : Configuration → ExtendedConfiguration     // reduce all steps
rule:
  * C → * C' if ○ C → C'                      // where C, C' are variables of sort Configuration

Figure 3.14: Representing small-step and many-step SOS reductions in rewriting logic

To obtain the reflexive and transitive many-step closure of the small-step SOS relation in the resulting rewrite setting and thus to be able to obtain an interpreter for the defined language when executing the rewrite system, we need to devise some mechanism to iteratively apply the one-step reduction step captured by rewriting as explained above. There could be many ways to do that, but one simple and uniform way is to add a new configuration marker, say \texttt{\textasciitilde}, with the meaning that \texttt{C} must be iteratively reduced, small-step after small-step, either forever or until an irreducible configuration is reached. Figure 3.14 shows how one can define both configuration markers algebraically (assuming some existing \texttt{Configuration} sort, e.g., the one in Figure 3.10). To distinguish the marked configurations from the usual configurations and to also possibly allow several “one-step” markers at the same time, e.g., “\texttt{○○○}”, which could be useful for debugging/tracing reasons, we preferred to define the sort of marked configuration as a supersort of \texttt{Configuration}.

Theorem 4. (Faithful embedding of small-step SOS into rewrite logic) For any small-step operational semantics definition \texttt{SmallStep}, and any \texttt{SmallStep} appropriate configurations \texttt{C} and \texttt{C'}, the following equivalences hold:

\[
{\texttt{SmallStep}} \vdash C \rightarrow C' \iff {\texttt{R_{SmallStep}}} \vdash ○ C \rightarrow^1 C' \iff {\texttt{R_{SmallStep}}} \vdash ○ C \rightarrow C'
\]

\[
{\texttt{SmallStep}} \vdash C \rightarrow* C' \iff {\texttt{R_{SmallStep}}} \vdash * C \rightarrow \ast C'
\]

where \texttt{R_{SmallStep}} is the rewrite logic semantic definition obtained from \texttt{SmallStep} translating each rule in \texttt{SmallStep} as above. (Recall from Section 2.7 that \texttt{→^1} is the one-step rewriting relation obtained by dropping the reflexivity and transitivity rules of rewrite logic. Also, as \texttt{C} and \texttt{C'} are parameter-free —parameters only appear in rules— \texttt{C} and \texttt{C'} are ground terms.)

Except for transforming “parameters” into “variables”, the only apparent difference between \texttt{SmallStep} and \texttt{R_{SmallStep}} is that the latter marks (using “\texttt{○}”) all the left-hand-side configurations and, naturally, uses conditional rewrite rules instead of conditional deduction rules. As Theorem 4 shows, there is a step-for-step correspondence between their corresponding “computations” (or executions, or derivations). Therefore, similarly to the big-step SOS representation in rewriting logic, the rewrite theory \texttt{R_{SmallStep}} is the small-step SOS \texttt{SmallStep}, and not an “encoding” of it.

Recall from Section 3.2.3 that in the case of big-step SOS there were some subtle differences between the one-step \texttt{→^1} (obtained by dropping the reflexivity and transitivity rules of rewriting logic) and the usual \texttt{→} relations in the rewrite theory corresponding to the big-step SOS. The approach followed in this section based on marking configurations, thus keeping the left-hand- and
the right-hand-sides always distinct, eliminates all the differences between the two rewrite relations in the case of the one-step reduction (the two relations are identical on the terms of interest). The second equivalence in Theorem 4 tells us that we can turn the rewrite logic representation of the small-step SOS language definition into an interpreter by simply marking the configuration to be completely reduced with a “\(\text{\textendash}\)” and then letting the rewrite engine do its job.

It is worthwhile noting that like in the case of the big-step SOS representation in rewriting logic, unfortunately, \(\mathcal{R}_{\text{SmallStep}}\) lacks the main strengths of rewriting logic: in rewriting logic, rewrite rules can apply under any context and in parallel. Indeed, the rules of \(\mathcal{R}_{\text{SmallStep}}\) can only apply at the top, sequentially. This should not surprise because, as stated, \(\mathcal{R}_{\text{SmallStep}}\) is \(\text{SMALLStep}\), with all its strengths and limitations. By all means, both the \(\mathcal{R}_{\text{SmallStep}}\) above and the \(\mathcal{R}_{\text{BigStep}}\) in Section 3.2.3 are rather poor-style rewriting logic specification. However, that is normal, because neither big-step SOS nor small-step SOS were meant to have the capabilities of rewriting logic w.r.t. context-insensitivity and parallelism; since their representations in rewriting logic are faithful, one should not expect that they inherit the additional capabilities of rewriting logic (if they did, then the representations would not be step-for-step faithful, so something would be wrong).

**Small-Step SOS of IMP in Rewriting Logic**

Figure 3.15 gives the rewriting logic theory \(\mathcal{R}_{\text{SmallStep}(\text{IMP})}\) that is obtained by applying the procedure above to the small-step SOS of IMP, namely the formal system \(\text{SMALLStep (IMP)}\) presented in Figures 3.11 and 3.12 As usual, we used the rewriting logic convention that variables start with upper-case letters, and like in the rewrite theory corresponding to the big-step SOS of IMP in Figure 3.8 we used \(\sigma\) (a larger \(\sigma\) symbol) for variables of sort \(\text{State}\). Besides the parameter vs. variable subtle (but not unexpected) aspect, the only perceivable difference between \(\text{SMALLStep (IMP)}\) and \(\mathcal{R}_{\text{SmallStep}(\text{IMP})}\) is the different notational conventions they use. The following corollary of Theorem 4 establishes the faithfulness of the representation of the small-step SOS of IMP in rewriting logic:

**Corollary 3.** \(\text{SMALLStep (IMP)} \vdash C \rightarrow C' \iff \mathcal{R}_{\text{SmallStep}(\text{IMP})} \vdash \sigma C \rightarrow \sigma C'.\)

Therefore, there is no perceivable computational difference between the IMP-specific proof system \(\text{SMALLStep (IMP)}\) and generic rewriting logic deduction using the IMP-specific rewrite rules in \(\mathcal{R}_{\text{SmallStep}(\text{IMP})}\); the two are faithfully equivalent.

\(\star\) **Maude Definition of IMP Small-Step SOS**

Figure 3.16 shows a straightforward Maude representation of the rewrite theory \(\mathcal{R}_{\text{SmallStep}(\text{IMP})}\) in Figure 3.15 including representations of the algebraic signatures of small-step SOS configurations in Figure 3.10 and of their extensions in Figure 3.14 which are needed to capture small-step SOS in rewrite logic. The Maude module \(\text{IMP-SEMANTICS-SMALLSTEP}\) in Figure 3.16 is executable, so Maude, through its rewriting capabilities, yields a small-step SOS interpreter for IMP the same way it yielded a big-step SOS interpreter in Section 3.2.3 for example, the command

Maude> rewrite * < sumPgm > .

where \(\text{sumPgm}\) is the first program defined in the module \(\text{IMP-PROGRAMS}\) in Figure 3.4 produces a result of the form (the exact statistics are also irrelevant, so they were replaced by “...”):
\[ \circ(X, \sigma) \rightarrow (\sigma(X), \sigma) \]
\[ \circ(A_1 + A_2, \sigma) \rightarrow (A'_1 + A_2, \sigma) \quad \text{if} \quad \circ(A_1, \sigma) \rightarrow (A'_1, \sigma) \]
\[ \circ(A_1 + A_2, \sigma) \rightarrow (A_1 + A'_2, \sigma) \quad \text{if} \quad \circ(A_2, \sigma) \rightarrow (A'_2, \sigma) \]
\[ \circ(I_1 + I_2, \sigma) \rightarrow (I_1 +_{\text{int}} I_2, \sigma) \]
\[ \circ(A_1 / A_2, \sigma) \rightarrow (A'_1 / A_2, \sigma) \quad \text{if} \quad \circ(A_1, \sigma) \rightarrow (A'_1, \sigma) \]
\[ \circ(A_1 / A_2, \sigma) \rightarrow (A_1 / A'_2, \sigma) \quad \text{if} \quad \circ(A_2, \sigma) \rightarrow (A'_2, \sigma) \]
\[ \circ(I_1 / I_2, \sigma) \rightarrow (I_1 /_{\text{int}} I_2, \sigma) \quad \text{if} \quad I_2 \neq 0 \]
\[ \circ(A_1 \leq A_2, \sigma) \rightarrow (A'_1 \leq A_2, \sigma) \quad \text{if} \quad \circ(A_1, \sigma) \rightarrow (A'_1, \sigma) \]
\[ \circ(I_1 \leq A_2, \sigma) \rightarrow (I_1 \leq_{\text{int}} A_2, \sigma) \quad \text{if} \quad \circ(A_2, \sigma) \rightarrow (A'_2, \sigma) \]
\[ \circ(\text{not } B, \sigma) \rightarrow (\text{not } B', \sigma) \quad \text{if} \quad \circ(B, \sigma) \rightarrow (B', \sigma) \]
\[ \circ(\text{not false}, \sigma) \rightarrow (\text{false}, \sigma) \]
\[ \circ(\text{not true}, \sigma) \rightarrow (\text{true}, \sigma) \]
\[ \circ(B_1 \text{ and } B_2, \sigma) \rightarrow (B'_1 \text{ and } B_2, \sigma) \quad \text{if} \quad \circ(B_1, \sigma) \rightarrow (B'_1, \sigma) \]
\[ \circ(\text{false and } B_2, \sigma) \rightarrow (\text{false}, \sigma) \]
\[ \circ(\text{true and } B_2, \sigma) \rightarrow (B_2, \sigma) \]
\[ \circ(X := A, \sigma) \rightarrow (X := A', \sigma) \quad \text{if} \quad \circ(A, \sigma) \rightarrow (A', \sigma) \]
\[ \circ(X := I, \sigma) \rightarrow (\text{skip}, \sigma[I/X]) \]
\[ \circ(S_1 ; S_2, \sigma) \rightarrow (S'_1 ; S_2, \sigma') \quad \text{if} \quad \circ(S_1, \sigma) \rightarrow (S'_1, \sigma') \]
\[ \circ(\text{skip} ; S_2, \sigma) \rightarrow (S_2, \sigma) \]
\[ \circ(\text{if } B \text{ then } S_1 \text{ else } S_2, \sigma) \rightarrow (\text{if } B' \text{ then } S_1 \text{ else } S_2, \sigma) \quad \text{if} \quad \circ(B, \sigma) \rightarrow (B', \sigma) \]
\[ \circ(\text{if true then } S_1 \text{ else } S_2, \sigma) \rightarrow (S_1, \sigma) \]
\[ \circ(\text{if false then } S_1 \text{ else } S_2, \sigma) \rightarrow (S_2, \sigma) \]
\[ \circ(\text{while } B \text{ do } S, \sigma) \rightarrow (\text{if } B \text{ then } (S ; \text{while } B \text{ do } S) \text{ else skip}, \sigma) \]
\[ \circ(\text{vars } Xl ; S) \rightarrow (S, (Xl \rightarrow 0)) \]

Figure 3.16: The small-step SOS of IMP in Maude, including the definition of configurations
Like for the big-step SOS definition in Maude, one can also use any of the general-purpose tools provided by Maude on the small-step SOS definition above. For example, one can exhaustively search for all possible behaviors of a program using the `search` command:

```
Maude> search * < sumPgm > =>! Cfg:Configuration .
```

As expected, only one behavior will be discovered because our IMP language so far is deterministic.

### 3.3.4 Notes

Small-step structural operational semantics was introduced as just *structural operational semantics* (SOS; no “small-step” at that time) by Plotkin in a 1981 technical report (University of Aarhus Technical Report DAIMI FN-19, 1981) that included his lecture notes of a programming language course. Interestingly, for more than 20 years this technical report was cited as the main SOS reference by hundreds of scientists who were looking for mathematical rigor in their programming language research. It was only in 2004 that Plotkin’s SOS was finally published in a journal [37].

There is a plethora of research projects and papers that explicitly or implicitly take SOS as the formal language semantics framework. Also, SOS served as a source of inspiration, or of problems to be fixed, to other semantic framework designers, including the author. There is too much work on SOS, using it, or modifying it, to attempt to cover it here. We only limit ourselves to directly related research focused on capturing SOS as a methodological fragment of rewriting logic, as we also did in this section. The marked configuration style that we adopted in this section to faithfully represent small-step SOS in rewrite logic was inspired from [43]; there, the configuration marker (“○”) was called “configuration modifier”. An alternative way to keep the left-hand- and the right-hand-side configurations distinct was proposed in [22]; the idea there was to use two different types of configuration wrappers, one for the left-hand-side of the transitions and one for the right-hand-side, yielding rewrite logic rules of the form:

\[
\{C\} \to \{C'\} \text{ if } \{C_1\} \to \{C'_1\} \land \{C_2\} \to \{C'_2\} \land \cdots \land \{C_n\} \to \{C'_n\},
\]
